# ENCYCLOPÆDIA BRITANNICA

## VOLUME XXXI

### THE SECOND OF THE NEW VOLUMES

---

**ENGLISH LITERATURE** (*see* 9.645*).—A retrospect, from the vantage-ground of 1921, over the progress of English literature in recent years showed no sign of degeneracy in literary quality. From a purely national point of view, English writers have probably never stood higher comparatively in the world of letters. The commerce of the book-world and the ply of the "best sellers" may vary; but if we regard the curve of literature as a whole, it is justifiable to claim that, during the past generation, the best English work has not been deflected from the direction in which literary progress had been steadily moving.

The acme of the English novel was reached already in the last quarter of the 19th century. And among novelists still living in 1921 Thomas Hardy held a position of lofty preëminence. In these later years his work as a poet had given him a second title to fame. Even more than in the case of his finest tragic novels, his tragic epic, *The Dynasts*, is full of a great pity and a great patience. Like all great tragedy it is cathartic. Like all great art, it exalts and enlarges.

In Sir J. M. Barrie, by origin a typical Scot, who, together with Hardy, had received the Order of Merit, fantasy had achieved its highest embodiment since *Midsummer Night's Dream*. Faërie had, in him, become naturalized on the English stage; and it has been for the theatre that all his later work was done—a constantly growing range of work, from *Peter Pan* to *The Admirable Crichton*, *Cinderella*, *What Every Woman Knows*, *Dear Brutus*, *The Twelve-Pound Look*, *The Old Lady Shows Her Medals*, and *Mary Rose*. Hardy and Barrie between them had created an atmosphere of the theatre in which it had become possible for an imagination worthy of English literature to move and breathe and have its being.

In the forefront of literary activity in 1921, the work of H. G. Wells and of Bernard Shaw, though less creative, sounded its challenge to the future—Wells as the sociological autobiographer of his time, Shaw as a satirist, often as bitter as Swift, and with something in him of a new Gulliver.

H. G. Wells's skill as a writer is shown in the almost animal realism of his presentment, not in one or two books merely, but a score. In his fiction he is specially autobiographic:

"I recall an underground kitchen with a drawered table, a window looking up at a grating, a back yard in which, growing out by a dust-bin, was a grape-vine; a red-papered room with a book-case, over my father's shop, the dusty aisles and fixtures, the regiments of wine-glasses and tumblers, the rows of hanging mugs and jugs, the towering edifices of jam-pots, the tea and dinner and toilet sets in that emporium, its brighter side of cricket goods, of pads and balls and stumps. Out of the window one peeped at the more exterior world, the High Street in front, the tailor's garden, the butcher's yard, the church-yard and Bromley church tower behind, and one was taken upon expeditions to fields and open places. This limited world was peopled with certain familiar presences, mother and father, two brothers, the evasive but interesting cat."

Upper-class life he saw (from the point of view of the servant hall) when on his father's death in 1878 his mother became housekeeper in the family in which she had formerly been lady's maid at Up Park near Petersfield, the "Bladesover" of *Tono-Bungay*, which also enshrines some early experiences in the chemist shop at Midhurst. He had a bitter struggle, both for livelihood and for education, beginning work as a draper's assistant at the age of 15, and experiencing in his own person some of the humiliations he has described in *Kipps*. Striving to educate himself, he took a humble post as assistant master in an obscure school, and from this in turn he escaped with the aid of a Government scholarship to the Royal College of Science, South Kensington. It was his good fortune to come under Huxley, the leading exponent of the new science of biology and one of the most stirring spirits in the intellectual unrest of the time. Economically and socially the immediate gain for Wells was the London B.Sc. degree with first-class honours in zoölogy; upon his mental development the effects were far-reaching. It is really of himself under the name of "Oswald" that Wells speaks in this passage from *Joan and Peter:*

"Those were the great days when Huxley lectured on zoölogy at South Kensington, and to him Oswald went. Oswald did indeed find science consoling and inspiring. Scientific studies were at once rarer and more touched by enthusiasm then than a quarter of a century later, and he was soon a passionate naturalist, consumed by the insatiable craving to know how. That little long upper laboratory in the Normal School of Science, as the place was then called, with the preparations and diagrams along one side, the sinks and windows along the other, the row of small tables down the windows, and the ever-present vague mixed smell of methylated spirit, Canada balsam and a sweetish decay, opened vast new horizons to him. To the world of the eighteen-eighties the story of life, of the origin and branching out of species, of the making of continents, was still the most inspiring of new romances. Comparative anatomy in particular was then a great and philosophical 'new learning,' a mighty training of mind; the drift of biological teaching towards specialization was still to come."

It was partly due to ill-health as a hard-worked young don that Wells turned his attention from the more scholastic region of scientific journalism and text-book to writing romance of the Jules Verne variety. In this he achieved a rapid success. It is still delightful for a reader to recall the thrill of first contact with *The Time Machine* and *Doctor Moreau's Island*, soon to be followed by *The Wheels of Chance*, and the *War of the Worlds*, in the middle and later 'nineties. Some critics will maintain that, in technical skill and professional drollery, Mr. Wells never surpassed *The Wheels of Chance* or *The Sea Lady*. In 1900, however, came *Love and Mr. Lewisham*, which was regarded as a landmark; but it was eclipsed in the direction of sociology of contemporary life by *Kipps* in 1905 and the more ambitious *Tono-Bungay* in 1909. Nor will the war-period in England be understood without *Mr. Britling Sees It Through*.

* *These figures indicate the volume and page number of the previous article.*

George Bernard Shaw, who was born in Dublin in 1856, came of English Protestant middle-class stock. "I am a typical Irishman," he says; "my family came from Yorkshire. My father was an ineffective, unsuccessful man, in theory a vehement teetotaller, but in practice a furtive drinker. I never learnt anything at school, a place where they put *Caesar* and *Horace* into the heads of small boys, and expect the result to be an elegant taste of knowledge of the world. I took refuge in total idleness at school, and picked up at home quite unconsciously a knowledge of that extraordinary literature of modern music from Bach to Wagner, which has saved me from being at the smallest disadvantage in competition with men who only know the grammar and mispronunciation of the Greek and Latin poets and philosophers. For the rest my parents went their own way and let me go mine." He combined the unaccustomed arts of critic, logician and sceptical journalist. He was haunted by wit, largely of the caustic variety of Samuel Butler (the author of *Erewhon*). The *conferencier* of a silken skein, he drew an audience like a magnet, but he ridiculed English ideas of a "sport" and a "gentleman," his unpopularity flaring in 1914 in a tract called *Common Sense and the War*. To him a typical Englishman was a wildly absurd and enthusiastic fellow (Nelson); Wellington, a typical common-sense Irishman, was better. Church and public-school ideas became his butts. He preferred the provocative method to any other. From critic and quasi-novelist he became playwright. His first play, *Widowers' Houses*, written in 1885, was not produced until 1892, and then with scant success. He followed this with *The Philanderer* (1893), a satire on the emancipated woman, and *Mrs. Warren's Profession*, a treatment of commercialized vice, which was refused performance by the censor. *Arms and the Man*, a brilliant satire on military glory, *Candida* (1894), *The Man of Destiny* (1895), a mock-heroic skit on Napoleon, and *You Never Can Tell* (1896), a farcical treatment of the New Woman, followed. These seven plays were all distinguished by their attack upon some time-honoured sham, their reduction to reality of some pretentiously false view. Perhaps because of their slight success as acting plays, Shaw published them in two series, *Plays Pleasant and Unpleasant* (1898). He made the prefaces to these volumes elaborate comments on the technical and social qualities of the plays; and, further to guide his readers, he expanded the stage directions into full descriptions, character sketches and explanations, thus adapting the play to a public which was accustomed to read novels. Prose drama was once more restored to the library. The later plays were more immediately successful on the stage, but Shaw continued to publish them as books, and, by the aid of the prefaces, to use them as effective propaganda for his views on art, the theatre, history and society. He attacks the illusion of history in *Caesar and Cleopatra*, and of romantic morality in *The Devil's Disciple*, published in *Three Plays for Puritans* (1900). In *Man and Superman* (1903) he represents courtship as a war of the sexes, and man as the victim of woman, who is the incarnation of nature's purpose and the will to live. In *John Bull's Other Island* (1904) he attacked English domination of Ireland, and made the preface a powerful arraignment of military rule in Egypt. He attacks poverty in Butlerian vein in the persons of those weak members of society who accept it, and looks forward to their extinction with the extension of a better race. The attitude, called "pragmatism," of accepting as true only beliefs that will work, is shown by his attack on the ideas of reform by punishment, or of the improvement of society by marriage and the home. In such volumes as *Androcles and the Lion* and, later, *Back to Methuselah*, he conversationalizes and essayizes at the same time, giving modern dialect the benefit wherever possible.

The psychology of the end of our period has forced us, more or less, to isolate these four outstanding personalities, Hardy, Barrie, Wells and Shaw, as representing the most dominant forces of contemporary influence. But an enumeration of other prominent living representatives of English letters in 1921 shows that there had been no falling-off in distinction since the century opened. A list of some 50 would find honoured veterans (Morley, Frederic Harrison, Bryce, Trevelyan) side by side with long-established critics in Saintsbury, Gosse, Sidney Colvin, W. P. Ker; dramatists in Pinero and Henry Arthur Jones; and, among the middle generation, writers of genius already fully recognized before 1900 in Rudyard Kipling, William Watson, W. B. Yeats, Alice Meynell and Robert Bridges. With them may be named, in alphabetical order:—Lascelles Abercrombie, Maurice Baring, Max Beerbohm, Hilaire Belloc, Arnold Bennett, E. F. Benson, Laurence Binyon, "George Birmingham," Augustine Birrell, John Buchan, G. K. Chesterton, A. Clutton-Brock, A. Conan Doyle, Joseph Conrad, W. H. Davies, Walter De La Mare, C. M. Doughty, Oliver Elton, John Galsworthy, Charles Graves, Rider Haggard, Maurice Hewlett, R. S. Hichens, Anthony Hope-Hawkins, A. E. Housman, W. H. Hudson, Stephen Leacock, Sidney Lee, W. J. Locke, E. V. Lucas, J. W. Mackail, Stephen McKenna, Compton Mackenzie, John Masefield, George Moore, Henry Newbolt, Alfred Noyes, Herbert Paul, A. Quiller-Couch, Walter Raleigh, George W. Russell ("A. E."), Owen Seaman, May Sinclair, De Vere Stacpoole, A. B. Walkley, Hugh Walpole, Margaret Woods, Israel Zangwill.

In fiction, preëminently among literary productions, the temporary displacements of popular vogue are numerous. During 1910–21, while the cult of Henry James and of Joseph Conrad had gathered strength, the genius of Rudyard Kipling had found no new utterance. The most characteristic writers of fiction during this period were Wells, Arnold Bennett, Galsworthy, Compton Mackenzie, Stephen McKenna, E. V. Lucas, W. J. Locke, W. L. George, Hugh Walpole, Gilbert Cannan and May Sinclair. A great change had come over the spirit of fiction and its frankness since the days of the eminent Victorians. "Psycho-analysis" had become its theme. Galsworthy's *Dark Flower* and *Beyond* are almost entirely taken up with the analysis of sex-attraction; Wells and Shaw are strangely intent upon the life-force; and with writers like Compton Mackenzie, W. L. George, D. H. Lawrence and Gilbert Cannan, it becomes almost an obsession. The emancipation for which the novelists of an earlier generation had sighed was achieved with a lack of effort that was almost instantaneous in the 20th century.

Yet withal, the humanitarianism of Galsworthy and the dramatic regionalism of Arnold Bennett have formed solid enrichments of the literary stock in English fiction. Note must be taken, too, as characteristic also of the two last-named, of a fine vein of literary epicurism in those contemporary writers to whom style is inseparable from ideas. Among novelists who are also essayists this has been a marked feature of the work of Hilaire Belloc and E. V. Lucas; hardly less marked in the case of Filson Young; most marked of all in that of George Moore, whose *Brook Kerith* and *Héloïse and Abelard* stand out as perhaps the most deliberately "artistic" pieces of English composition in the period. The epicurism of George Moore is even more definitely embodied in those intimate records of his Irish literary associations (*Hail and Farewell:—Ave; Salve; Vale*) which may well be, to a later generation, more interesting than anything in his fiction. Nor from this selection of contemporary epicures in style can reference be omitted to the writings of Max Beerbohm (*Works; More; Yet Again; A Christmas Garland; And Even Now*)—an ironist of delightful fastidiousness.

England is proud of her ironists. When Samuel Butler, the author of *Erewhon*, died in 1902, his views were set forth in the posthumous novel, *The Way of All Flesh*, one of the seminal satires of to-day. In his union of logic with irony Butler belongs with Huxley and Matthew Arnold, as he is their peer in the mastery of a superbly clear and idiomatic English style. He differs from them in that he possessed also a certain gnome-like impudence of fancy, which led him into strange ambiguities and throws a veil of seeming irresponsibility over much of his writing.

Outside fiction, it is remarkable how much of the wealth of English *belles lettres* has revolved round historical biography and world history, as systematized in great men and "heroes." The conclusion of Swift that history was formed by the essence of innumerable biographies may indeed seem to have been demonstrated in recent years by the production in England of the *Dictionary of National Biography* and by such individual cases as

G. E. Buckle's completion of the *Life of Disraeli*; while Lytton Strachey's re-readings in biography (*Eminent Victorians* and *Queen Victoria*) have added a new interest to its study.

In tracing the contemporary developments of English poetry, it has been said that the "aesthetic" movement of the 'nineties came more or less definitely to fill the void caused by the ebb-tide of Tennyson, Browning, Rossetti and Morris. Swinburne and Meredith, Bridges and William Watson, may be added to these names of poets already established by the end of the 19th century. In 1855, when Tennyson was crowned by the young men of England at the Sheldonian, poetry was "the thing," and this was due to Tennyson. Tennyson had, indeed, invented a new poetry, a new poetic English; every piece that he wrote was a conquest of a new region. The early attitude of Morris to Tennyson is described by Morris's biographer as defiant adoration. He perceived his limitations, however, in a manner remarkable for a man of twenty or so. *Sir Galahad* made too much noise and was not nearly mediaeval enough for him. The rise and reign of the Browningesque and the picturesque followed—the decay of Victorianism as a purely decorative art. Then came the rise and decline of the aesthetic philosophy in the 'nineties, with the introduction of the muscular influence of Henley, Kipling, Davidson, Henry Newbolt, and, still more recently, Masefield, to whom have been added all those included among the Georgians. And yet there is no abrupt period of severance. *A Shropshire Lad*, written when A. E. Housman (b.1859) was little more than thirty, is not the most easy of modern verse, but is still the best-loved when it is most read. Robert Bridges' early poems include lyrics which are among the most perfect work, in magic of cadence or in formal prosody, since Carew, Wither and Herrick.

The conspicuous poets among the Georgians are not, perhaps, of the first rank, but far more than in the last century they are poets of democracy. They are poets of a diversity of ideas, and are acclaimed, as often as not, for refusing imaginative idylls in order to write of the common sights and sounds of the everyday world in which we live. Among the new poets are included Lascelles Abercrombie, C. M. Doughty, Sturge Moore, Belloc, Chesterton, W. H. Davies, A. Noyes, L. Binyon, James E. Flecker, Edward Thomas, Rupert Brooke, W. W. Gibson, Ralph Hodgson, John Masefield, W. De La Mare, John Freeman, Siegfried Sassoon, J. C. Squire.

In 1895 the *Yellow Book* sought to shock the primness of the "eminent Victorians," as they came to be satirized. It scarcely needed *Patience* or *The Green Carnation* to disillusion the attitudinizing of A. Symons, Le Gallienne and their disciples. With the end of the century the philosophy of the aesthetes was wearing thin. The "Yea Man" and muscular Christian repudiated this languid aestheticism ("The first duty of life is to be artificial"). But it was reinforced to some extent by the "Celtic revival" (you could hardly obtain a more artificial adjective than that), as represented by W. B. Yeats. Remarkable work in the Spenserian vein was achieved by Charles Montagu Doughty (b.1843), whose *Dawn in Britain* (1906) reacts against Victorian feeling as Walpole reacted against Brunswick. These constant reactions are typical of an over-studied literature. It needs the architecture of Hardy to surpass it in *The Dynasts*. The distant and almost planetary point of view taken in the immense poetic dramas is contradicted most exhaustively by John Masefield (b.1874), a "Shropshire Lad" in reality, who scorned the finished elegiac of Housman and the minute tedium of the novel for the Crabbe-like medium of *The Everlasting Mercy* (1911) and for the counterpoise to the Celtic dialect play in *The Tragedy of Nan*. Of Masefield's realistic novels in verse the best is probably *Dauber* (1912). Versatile though he is, he has never completely succeeded in developing the irony of circumstance so exactly as Hardy; but he has drawn others into it, like Lascelles Abercrombie, who in *Deborah* (1913) achieves a fine approach to the Miltonic drama. The change that was foreshadowed in the unequal *Daffodil Fields* (1913) was completed by the battlefield and the great telling of *Gallipoli* (1916). Thence Masefield's prose and verse suffered a war change, and with it his writing gained in poetry and true utterance. In *August 1914* he reached a noble elegy:—

> These homes, this valley spread below me here,
> The rooks, the tilted stacks, the beasts in pen,
> Have been the heart-felt things, past speaking dear,
> To unknown generations of dead men.

Of poets lost during the war, memories of their craftsmanship is perhaps most insistent in the case of Rupert Brooke (1887–1915) and Edward Thomas (1878–1917).

Edward Thomas, one of the little-known but most individual of modern English poets, was born in 1878. For many years before he turned to verse, Thomas had a considerable following as a critic and author of travel books and biographies. Hating his hack-work, yet unable to get free of it, he had so repressed his creative ability that he had grown doubtful concerning his own power. It needed something foreign to stir and animate what was native in him. So when Robert Frost, the New England poet, went abroad in 1912 for two years and became an intimate friend of Thomas, the English critic began to write poetry. Loving, like Frost, the *minutiae* of existence, the quaint and casual turns of ordinary life, he caught the magic of the English countryside in its unpoeticized quietude. Many of his poems are full of a slow, sad contemplation of life, and reflection of its brave futility. It is not disillusion exactly; it is rather an absence of illusion. *Poems* (1917), dedicated to Robert Frost, is full of Thomas's fidelity to little things, as unglorified as the unfreezing of the "rock-like mud," a child's path, a list of quaint-sounding villages, birds' nests uncovered by the autumn wind, dusty nettles—the lines glow with a deep and almost abject reverence for the soil.

In 1913 Rupert Brooke, of Grantchester, was elected a fellow of King's College, Cambridge, aged 36. After travel and recreation he sought fresh faith and hope in the struggle. After seeing service in Belgium (1914) he spent the following winter in a training camp in Dorsetshire, and sailed with the British Mediterranean Expeditionary Force in February 1915, to take part in the Dardanelles campaign. Brooke never reached his destination. He died of blood-poisoning at Skyros, April 23 1915.

Another poet whose early death extorted a rare eulogy from a fellow writer, D. Goldring, was James E. Flecker (1884–1915), a student of André Chenier and later of the Parnassians, whose beatified dreams sing in the *Golden Journey to Samarkand* (1913) and *The Old Ship*. His *Burial in England Ode* shows noble evidence of a faith to which English witnesses were many.

Events in Ireland have emphasized the increased attention devoted of late years to the Irish literary revival (*see* IRELAND: *Language and Literature*). Anglo-Irish literature had its beginning in the early days of the 19th century, but it was not until about 1840 that there was a definite movement for the re-creation of an Irish culture in English. This movement was forwarded by Thomas Davis, and it took its title from Davis's newspaper, *The Nation*. There were many eloquent writers then in prose and verse. Carleton, the Banims and Gerald Griffin were the novelists of the time; Mangan, Ferguson, Davis, Walsh and Cullinan were the poets; Mitchell and Davis were the political and social writers. But while Davis and his group were working for the creation of a new Irish culture, the famine of 1846–7 altered the whole life of the country. Meanwhile, from the *Nation* period, when the poet Mangan worked with the scholar O'Donovan to produce versions of the Irish bardic poems, there had been a close connexion between Celtic research and Anglo-Irish poetry. The most valuable poetry written in the next forty years came from Celtic originals or from suggestions in Celtic originals. Sir Samuel Ferguson, who survived from the *Nation* days, treated the famous "Ultonian" or "Red Branch" epic cycle (the cycle that has the hero Cuchullain for its central character) as Tennyson was treating the Round-Table cycle, writing narrative or dramatic poems about the different episodes. He translated a few of the modern folksongs, bringing into English poetry an unfamiliar rhythm in such versions as those of *Cean Dubh Deelish* and *Carbel of Munster*, poems that have the beauty and the spirit of the originals. Aubrey de Vere wrote Catholic poetry, but the two poems by him that deal with

Celtic life in Ireland, *Bard Eithell* and *The Wedding of the Clans*, represent his strongest work. Dr. Sigerson, in his generation, made metrical translations of Irish poetry from the 8th to the 18th century, and his collection, *Bards of the Gael and Gall*, was an important influence on the new Irish poetry.

With the 'eighties came a period of social and political conflict in Ireland. But out of the political welter emerged the Gaelic League. And it was this organization that henceforth provided a soil and a shelter for the new poetry, although this new poetry was still to be in English.

It must be said, however, that, despite the heroic activity displayed during well-nigh thirty years, the Gaelic movement as such, with its classes, societies, athletic clubs, readings and revivals, represented in 1921 something of a provincialism, with its future (to use a Hibernicism) rather behind it than before it. The Gaelic School is remarkably lacking in Irish jollity. The historic Irishman of literature, as shown by Moore, Thackeray, Lover, Lever, "George Birmingham," Somerville and Ross, has managed somehow to survive any modern Celtic presentment. At no time has Irish poetry as a whole been distinctly national; and the epithet "Celtic" is a misnomer if it be used to appropriate to Irish poets the characteristics of brooding melancholy, wistful mysticism and fervent idealism. The inspiration of the Irish poets is at least as much climatic and local as racial. It is no depreciation of the work done by Irish writers in recent years, aggressively self-conscious and artificial though much of it is, to say that, even in those faculties more peculiarly attributed to the Celt, he has never approached the depth and breadth of the Teuton; the whole literary output of the "Celtic fringe," so called, sinks into insignificance in comparison with the work of the Teuton and the Saxon.

The unbiassed observer who does not allow his vision to be blurred by the rose-coloured haze that wraps the propaganda literature of Sinn Fein will indeed have no hesitation in declaring that, judged by its own aims and ideals, the Gaelic movement has, on the whole, been a failure. Gaelic may indeed survive and may even prosper, although the fruits of its revival as a language are likely to remain inaccessible to all but the elect,—but it can never dominate, least of all will it be able to oust its rival, English. The odds are too great on the other side. This does not mean, of course, that the movement has been barren of results. It has provided a meeting-ground for thousands of Irish men and women who prior to 1893 seemed almost hopelessly separated by their own local political or sectarian associations. It has helped to bring to light again the old world of ancient Ireland from its manuscript tomb in Irish and Continental libraries. More important than this, it has circulated the glad news that there is indeed a native Irish literature, and an Irish tradition.

Such as it is in Irish literary circles, the group of writers which stands for distinct contemporary ideas is of almost exactly the generation of H. G. Wells, John Galsworthy and Arnold Bennett—W. B. Yeats (b.1865), George W. Russell ("A. E."), Douglas Hyde, Standish O'Grady, J. M. Synge and George Moore. The linguistic and dry-as-dust part, but much also that stands for the Irish Ireland idea—that is for an Irish-speaking, -writing and -thinking country—is mainly due to Hyde and O'Grady. But much also is due to the counter-influence of George Moore and of J. M. Synge, the latter of whom wrote unrivalled dialect, often poetic but often, too, rather quizzical comedy.

For a good many people, Protestant and un-Irish in speech, the most self-conscious representative of the group, artificial though he be, William Butler Yeats, is, nevertheless, the indicating number of the Celtic revival. None of Yeats's lyric rises perhaps to the plane of the more inspired lines of "A. E." or the happier dialectic efforts of J. M. Synge, but in three poems of his earlier period, *The Wanderings of Oisin* (1889), *The Countess Cathleen* (1892) and *The Land of Heart's Desire* (1894), Yeats has conceived and written something which is peculiarly his own. In the volume of *The Wind among the Reeds* (1899), Yeats reaches his finest and most original work in shorter lyrics. Yeats's mystical broodings of spirit lie outside the highway of poetry. They are as unintelligible to the common mind as the arcana of Blake. But Yeats has lived among men, and he is not guiltless of conscious artifice where Blake would have been wholly natural. Perhaps the most beautiful poems of the volume are "The Host of the Air," "Into the Twilight" and "The Song of Wandering Angus." The first-named, considered only as prosody, does not come short of "The Lake Isle of Innisfree."

The year 1899 not only saw the publication of *The Wind among the Reeds;* it found the poet busied with the workings of the Irish Literary Theatre, and it marked a point of declination in his lyric powers. *In the Seven Woods* (1903) contains no poetry as individual as the preceding volume, though it includes the stirring stanzas of "Red Hanrahan's Song," a poem which, with splendid imagery of clouds, winds, yellow pools and flooding waters, breathes the love of Ireland's bare hills, bog waters and warm soft rain. Other songs, however, suggest English and Elizabethan rather than Celtic models. The short series of love poems printed in *The Green Helmet* (1910) is metaphysical and not very distinctive; in *The Wild Swans of Coole* (1919) Yeats touches again the old melodies skilfully, but in the mood of an imitation of his earlier self. If not altogether with the short lyric, with poems of a different kind Yeats has shown himself the poet of an esoteric beauty, in a character and a manner that are all his own. Further, the three poems already mentioned may be regarded as the prelude to Yeats's phase as a dramatic poet. The first of these is in form derived from the Middle Irish dialogues of St. Patrick and Oisin, and represents the mythical hero relating to the saint the story of his wanderings in the paradises of pagan mythology, and his passionate love of Niam. The most striking characteristic of this early poem is that magical impression seldom surpassed or even approached in the modern mythology of poetic dream. We are caught once more in the faërie to which Huon of Bordeaux, of the mediaevals, primitively introduced the mechanicals of Athens.

George W. Russell, whose work appears under the monogram "A. E.," is, in the proper sense of the word, a mystic, though mysticism is scarcely a characteristic of the Irish; the Irish mind is rather intellectual than mystical. Like all mystics he is content to express a single idea. In all his volumes of verse, in *Homeward*, in the *Earth Breath*, in the *Divine Vision*, he has put into pregnant verse his all-sufficing thought. Men are the strayed heaven-dwellers—the angels who "willed in silence their own doom," the Gods who "forgot themselves to men." Involved in matter, now they are creating a new empire for the spirit. He has been drawn, too, to the study of Celtic remains; the old Irish mythology seems to him a fragment of the doctrine that was held by the Egyptians, the Greeks and the Indians. He alludes to the Irish divinities as if they were as well known as Zeus or Eros or Apollo. He is the mystical poet of our civilization, and nearly all of what the West has found in the Indian poet, Rabindranath Tagore, is in the poems of "A. E."

In the 'nineties the ascendancy of the national drama of Norway made a few Irish writers, W. B. Yeats, George Moore, Edward Martyn, think of experimenting with a national theatre for Ireland. They began by producing in Dublin, for three successive seasons, plays written by Irish writers but presented by English actors. The experiment closed unsuccessfully in 1901. Meanwhile the activities of the Gaelic League and other national societies had produced a company of Irish players. The company was now ready to further any experiments that Yeats, as the leader of the Irish dramatic movement, might make. Yeats brought into the company a writer who was to elucidate the movement, John M. Synge (1871–1909). Synge wrote six plays for the Irish theatre, five of which they produced, *The Shadow of the Glen*, *Riders to the Sea*, *The Well of the Saints*, *The Playboy of the Western World* and *Deirdre of the Sorrows*,—the last a powerful dramatization of the Exile of the Sons of Usnech, which forms one of the three "Sorrows of Story Telling" and has persisted in Irish tradition for at least a thousand years.

Amid the outpouring of new books, pointing in no special literary direction, creative English literature at its best, viewed from the standpoint of 1921, showed a stability of purpose, fundamentally unaltered by the advent of new ideas. In spite

of the whirlpools of Armageddon, the old Laboriositas was returning to the book-world. The St. John the Baptist, moreover, of a series of events without a parallel in human annals had been a representative, and a very perfect one on the whole, of English *belles lettres*. John Locke, Smollett, Edmund Burke, in earlier days, had all been pointers of remarkable accuracy where mighty events were concerned; but they have been surpassed in our own day by George Meredith, as a forerunner of the world-upheaval. The whole of his prose work is topical to the main end. His greatest novel was most political and most prophetic. In military matters he claimed none of Mr. Wells's technique nor of Mr. Shaw's "common sense." But he had the advantage of knowing something about history, and he has written more to the point than any historian.

In May 1909 Hardy wrote memorably:—

> He spoke as one afoot will wind
> A morning horn ere men awake.
> His note was trenchant, turning kind.
>
> He was of those whose wit can shake
> And riddle to the very core
> The counterfeits that time will break.
>
> So that, when now all tongues declare
> His shape unseen by his green hill,
> I scarce believe he sits not there.
>
> No matter. Further and further still
> Through the world's vaporous vitiate air
> His words ring on—as live words will.

It is interesting to note that Thomas Hardy, Meredith's successor in the leadership of English letters, owed the form of his *Desperate Remedies* greatly, as it happened, to Meredith, the publisher's reader. But Meredith himself, curiously enough, was "afflicted by Hardy's twilight view of life." "Twilight view of life" is an extraordinary charge for Meredith to bring. If Hardy does not dwell upon happiness, something must be allowed for temperament; he is vocal to tragedy rather than to joy. He must not be held "unperceiving because undemonstrative." To dwell on happiness is, simply, not his business. To Hardy the world is very old, and the life of man is very brief. The Romans used to think and talk in Casterbridge as men do to-day; over Egdon Heath the generation of men pass ceaselessly and leave no trace. Men and women are always snatching at happiness, striving to express and to fulfil themselves, and breaking themselves against a power that takes no heed of them. The structure of Hardy's work, as became an architect, is unspeakably superior to Meredith's; and in spite of *Jude*, his style is never really "obscure." In reading the pages of *Two in a Tower* one is struck by the pure beauty of the prose. And Hardy, although determinist, is never a real pessimist. Watching from infinity, he shows human life as futile and trivial. But when individuality is intensified and desire exerted, as in the love of man and woman, then, despite the hostility or indifference of the governing power, we see human life heroically grand. There is no trace of contempt, except in case of life's "little ironies." The charge of pessimism cannot stand. In the normal view of passion and in the glorious view of rustic philosophy and humour, Hardy is Shakespearean at his best, just as Barrie, his nearest younger rival in English letters, is Shakespearean in his eerie twilight glimpses of faërie. In their successive preëminence the quality of English literature has been worthily maintained. (T. Se.; H. Ch.)

**ENNEKING, JOHN JOSEPH** (1841–1916), American painter (*see* 9.647), died at Hyde Park, Mass., Nov. 17 1916.

**ENVER PASHA** (1881– ), leader of the Young Turks, was of very humble origin. He was born in Abana, near the Black Sea, where his father was a bridge-keeper and his mother followed the despised profession of laying out the dead. His father was Turkish, his mother Albanian, and he had a Circassian grandmother. He entered the Turkish army as a subaltern without money or influence but gained admission to the staff college at Constantinople, and from there went to Salonika, the headquarters of the Young Turk movement. He fought with Bulgarian and Greek guerrilla bands, coming meanwhile in contact with the representatives of the new ideas, and finding in Talaat, the miner telegraph official, a politician after his own heart. In 1908, as aide-de-camp of Gen. Hussein Hilmi, he, with Niazi Bey, imported the flag of revolution in the Macedonian mountains, originally with the object of restoring the constitution of 1876, which had been disregarded by 'Abdul Hamid, but also to save himself from a threatened arrest. 'Abdul Hamid professed to yield and Enver entered Constantinople as a feted hero. But he realized that his time was not yet come. He went to Berlin as major and military attaché, and there, from 1909 to 1911, he pursued his military studies and enjoyed a social career as a ladies' favourite. His stay was only once interrupted, when, in 1909, he hastened to Salonika, and with Mahmud Shevket undertook a brief and victorious campaign against the reactionaries, who hoped to regain unfettered power under 'Abdul Hamid. After taking the capital and deposing 'Abdul Hamid, Enver returned to Berlin. Having learned to speak good German, he took command at Benghasi in the Italo-Turkish War. He also wrote a book called *Tripoli*, dealing with this period.[1] The Peace of Lausanne brought his work in Africa to an end, and he returned to Constantinople to find Turkey in the midst of the war with the Balkan States. During the Dec. armistice, Enver, then a lieutenant-colonel, was made chief-of-staff of the X. Army Corps, of which he soon was virtually in command. His attempt at a landing at Sharkoi (in the E. of the Gallipoli peninsula), on Feb. 8 1913, miscarried, as indeed did all Enver's military enterprises. During the peace negotiations, when Kiamil, as Grand Vizier, took the wise course of deferring to the wishes of the British, Enver with his friends arrived in front of the Sublime Porte, shot the War Minister, Nazim Pasha, turned out Kiamil, forced himself upon the Sultan, and in collusion with the Young Turk Committee filled all the offices with Young Turks.

The new Vizier, Mohamed Shevket, was assassinated in June 1913, and this further enraged the Committee against the Old Turks and the Union Libérale. The body of the state was now purged of all elements which would not blindly carry out the policy of the Committee. More than 1,200 officers, among them 153 generals and colonels, were dismissed by Enver in one day. Enver put himself at the head of the troops, and in July 1913 made a triumphal entry into Adrianople, which had already been evacuated by the Bulgarians. On Jan. 3 1914 he promoted himself major-general and made himself Minister of War.

Now began a period of hasty measures and reckless decrees. At one time the Turkish script was altered, with the result that officers were unable to read their reports or orders; then the Enverie, a highly unpractical head-covering, reminiscent of a child's paper hat, was invented and introduced; in March 1914 he demanded and obtained the hand of Princess Nadjie, the Sultan's niece, made himself general of a division, and began, moreover, to take thought for his financial future. When at last he was forced to flee from Constantinople, the bridge-keeper's son owned 320 houses in the city, and he had also acquired interests in banks and mines.

When the World War broke out Enver began to cherish strategical ambitions. In the winter of 1914–5 he led an entire Turkish army in the disastrous offensive in the snow-covered mountains on the Russo-Turkish border. With Liman von Sanders, the chief of the German military mission, his relations were strained, and the situation was not improved by certain Germans who flattered Enver and intrigued against Liman von Sanders. He became a megalomaniac to whom no one dared offer a word of advice. He had no share in the Dardanelles defence, but took all the credit for it. In internal politics he became, by degrees, the absolute ruler of the country. When the Turkish collapse came, he fled by way of Odessa to Germany. In 1919 he was condemned to death at Constantinople *in contumaciam*. In the same year, after a brief exile among friends in Germany, he fled to Russia. There at first he helped Denikin to maintain the independence of the Caucasus, but when the latter made a political approach towards the Entente, Enver left him, stayed for a short time in Azerbijan, and was mixed up

[1] A German version was issued in 1918.

in adventures in Asia Minor. He was reported in 1920–21 to have been employed at Moscow as director of the Asiatic department in the Soviet Government, and to have posed at the Baku Congress of Oriental Peoples as the leader of a great Socialist movement in the middle east and north Africa.

**EPIDEMIOLOGY.**—In recent years more study has been given to that branch of the science of medicine which, under the name of epidemiology, displays the general factors which operate upon populations or aggregates and lead to the outbreak of a sickness affecting several persons within a short interval of time. The unit of the epidemiologist is a population, while the unit of a physician is an individual.

The first scientific epidemiologist was Hippocrates, whose treatises *On Epidemics* and *On Airs, Waters and Places* remain models of epidemiological inquiry. In the latter work, he displayed the correlation between the physique, habits of life and climatological advantages or disadvantages of various populations and the types of illness prevalent amongst them. In the former, by means of an intensive study of the diseases prevailing through a series of years in one and the same place, he established the conception of an epidemiological type or *constitution* determined to a greater or less degree by meteorological conditions. Incidentally Hippocrates described some forms of epidemic disease, such as mumps, in terms fully applicable to modern experience. He also recognized the tendency of particular types of epidemic sickness to appear at a change of season, especially near the vernal or autumnal equinox. In treating of disease as a mass phenomenon, of epidemics, Hippocrates exhibited the scientific caution and zeal for the collection of objective data upon which to found an induction which have rendered immortal his clinical studies. Galen, whose authority for many centuries overshadowed that of the founder of Greek scientific medicine, systematized the theoretical teaching of Hippocrates but recorded few fresh observations. According to Galen, a disease was a function of three variables: the innate or acquired constitution (crasis or temperament) of the body, disordered habits of life, atmospheric changes (metastases). Illness became epidemic when, some abnormal modification of the atmosphere having occurred, the temperaments, or crases, of a sufficient number of the persons exposed were apt to give rise to illness. He recognized the contagious nature of certain diseases, such as ophthalmia and phthisis, but, in his terminology, contagion was very different from what we now understand by it. He had no notion of a vital infective principle, a *contagium vivum*, but looked upon the transmission of disease from person to person more as one now looks upon the setting into vibration of a series of tuning-forks when their fundamental notes are struck. None of the post-Galenical or Greek physicians or of the Arabian writers added much to our practical knowledge of epidemiology. In the 16th century, Girolamo Fracastoro (1483–1553) clearly enunciated the principle of *contagium vivum* and, in the next generation, Guillaume Baillou (1538–1616) in his *Epidemiorum et ephemeridum libri II.* (first printed in 1640) resumed the plan of actually describing the forms of illness prevalent in successive years which was the foundation of Hippocratic epidemiology.

Neither the importance of Fracastoro's principle nor the value of the method originated by Hippocrates and adopted by Baillou were realized by contemporary physicians, and, although accurate description of particular outbreaks accumulated during the 17th century, a general science of epidemiology was still to seek.

The honour of being the second founder of scientific epidemiology is usually assigned to Thomas Sydenham, and although this physician had no notion of the importance of Fracastoro's ideas and in his adoption of the Hippocratic plan had been anticipated by Baillou, the attribution is just.

To Sydenham (1624–89) belongs the credit of having realized that the succession of diseases is not chaotic and of having attempted to deduce from personal observations extended over more than 20 years a general doctrine of epidemiology. Sydenham's observations are not always clearly recorded, nor were his conclusions entirely free from inconsistencies, but his main principles were the following. He thought that all types of disease prevalent at any one time bore the imprint of a common "constitution"—the ultimate source of which he supposed to be indefinable telluric variations—the overt expression of the constitution was a "stationary fever," found in different clinical settings. Hence two different specific "diseases" prevailing during one "constitution" resembled one another more closely than did instances of the same "disease" observed under two different "constitutions." To this distinction he attached the greatest importance as a practitioner of medicine:—"This only, fortified by a multitude of exact observations, I do confidently hold, that the aforesaid species of disease, in particular the continued fevers, may vary so enormously that you may kill your patient at the end of the year by the method which cured sufferers at the beginning of it."

Sydenham classified his successive "constitutions" in accordance with the clinical form of illness most usually observed under it and closely watched the changes of symptomatic form which heralded the emergence of a new "constitution."

Although in modern times this notion of an epidemiological succession has been a fruitful hypothesis and many of Sydenham's predictions as to the decline of reigning diseases and their replacement by others have been accurately fulfilled, his immediate influence upon epidemiological thought was much less effective than his moulding of clinical practice. The reason is that to sift the wheat from the chaff of his ideas required a new instrument, viz. a statistical method applied to numerical data. Neither method nor adequate data existed at the end of the 17th century. The science of epidemiology owes almost as much to Sydenham's contemporary, the London draper John Graunt (1620–74), who founded vital statistics, as to the English Hippocrates. During the 18th century some annalists of sickness, especially the elder Wintringham (1689–1748), Huxham (1692–1768), Van Swieten (1700–72) and Anton Störck (1731–1803), provided more data on the Hippocratic model, and practical contributions to the art of hygiene and the control of particular epidemics were made by such investigators as Lind (1716–94), Pringle (1707–82), Monroe (1727–1802), Brocklesby (1722–97) and Blane (1749–1834). Contemporaneously, a series of illustrious mathematicians, from Pascal to Laplace, were forging the instruments of statistical research which in the hands of Farr were destined to render great advances in scientific epidemiology possible. It cannot, however, be said that the general doctrines of epidemiology were notably improved or that the opinions entertained by physicians at the beginning of the 19th century differed greatly from those of their predecessors.

During the first 30 years of the 19th century unrivalled opportunities were afforded for the study of particular epidemic diseases, especially typhus and typhoid, owing to the Napoleonic Wars and the industrial revolution with its attendant social disorganization. A new interest in public health matters, especially in England, led to the accumulation of facts respecting the circumstances attending the outbreak of epidemic diseases. Before the establishment of the English General Register office (in 1837) official reports upon epidemiological matters, particularly cholera, had been furnished and the ground prepared for the work soon to be undertaken by William Farr (1807–83).

Broadly speaking, the state of epidemiological knowledge at the beginning of the reign of Victoria was as follows. The contagious nature of the diseases known as zymotics was fully recognized and the specific difference between scarlet fever and diphtheria understood. The relation between pollution of water supplies, cholera and certain other forms of "continued fever" with intestinal lesions had also been perceived. Experience of vaccination had firmly established a belief in the possibility of immunizing mankind against one form of epidemic disease. At least one physician, Robert Watt, of Glasgow (1774–1819), had contributed new evidence of a statistical character in favour of Sydenham's doctrine of epidemiological succession, while the remarkable increase of malignity which began to characterize scarlet fever during the third decade of the century and the return of pandemic influenza (a disease described by many writers in and before the 18th century) had impressed the same ideas upon the general body of the medical profession. On the other hand, the fundamental distinction between typhoid and typhus fever and the epidemiological importance of the distinction had only been realized by a few exceptional men, and statistical data necessary for the assessment of the epidemiological factors common to groups of diseases and for the testing of epidemiological theories were fragmentary.

*The Spread of Epidemics.*—Modern epidemiology is based on the collections of statistics which began half way through the 19th century, and on the associated information which was obtained as to the causation and course of epidemics by careful local inquiry into all the conditions. It is true that before this some countries, such as Sweden, had published the figures of the deaths from numerous infectious diseases for series of years, but though these figures are very interesting they represent more or less special conditions. Since about 1840, especially in Europe, in India and America, carefully collected information exists respecting many epidemics and epidemiological conditions. Sufficient evidence is now available to examine any theory which may be offered to account for the facts. Advance has been made on a number of lines: on the modes of spread of infection; on the theory of the course, recurrence, and size of epidemics; on the relation of epidemics to climatic conditions and the cause of these relations; on the knowledge of the life history of the organisms

which cause epidemics; on the conditions of living which favour the spread of infectious disease.

With the discovery of the organisms which cause disease and with the careful observation in the field as to the manner in which disease spreads from person to person, many new points of view have emerged. It is no longer sufficient to talk vaguely of fomites. Most diseases have their special forms of spreading which account for practically all the cases. Thus measles and smallpox are exceedingly infectious from person to person. Enteric fever is nearly always carried by contaminated water or contaminated food. Cholera is spread by water and flies. Other diseases have been found to be practically non-infectious from person to person unless by means of an intermediate parasite. Thus typhus and trench fever are carried by lice, while yellow fever and malaria require the intervention of the mosquito. The mode of spread of some diseases, however, is still obscure. Among these scarlet fever must be placed. While direct infection undoubtedly takes place a satisfactory elucidation of the problems of its dissemination has not yet been arrived at.

For accurate thinking on infectious diseases it must be noted that disease-producing organisms possess two qualities: one, the power of causing the disease, and the second the power of producing a severe attack of disease. The first may be termed infectivity and the second virulence. These qualities must not be confused. In point of fact they are not associated in any constant degree. Sometimes an epidemic begins with a large number of severe cases and sometimes the reverse. In certain diseases the height of the epidemic seems to be associated with severe disease, in others with that of milder type. The former at least holds for a certain number of large epidemics of measles of which the statistics have been investigated. The latter is the case both in Glasgow and London in regard to the autumnal prevalence of scarlet fever.

That an epidemic might possess a definite form capable of calculation seems to have been advanced first by Dr. Farr. In 1840 he graduated the decline of the great smallpox epidemic in England to the normal curve of error, and obtained a very close representation of the facts. He promised further discussion but seems to have given none till 1867. In this year he returned to the subject in connexion with the cattle plague, writing a letter to the *Daily News* in which it was stated that though in the popular conception plague was advancing with such rapidity that all the cattle of the country might be destroyed, in reality the force of the epidemic was spent, and that if the form of the epidemic curve up to that point were taken as a basis of calculation the future course could be foretold. The prediction proved to be very near the truth.

The theory of the course of the epidemic, however, as a guide to the solution of the problem has unfortunately not proved so fertile as might have been hoped. Some facts are quite definite. The curve of the epidemic is generally found to be symmetrical, the fall corresponding closely to the rise, though in some diseases the ascent is more rapid than the descent, and in some the reverse. The equation of the curve which describes the majority of epidemics, as found by trial apart from theory, is

$$y = \frac{a}{\left(1+\frac{t^2}{b^2}\right)^n}$$

where $y$ is the number of cases at time $t$, $t$ being measured from the centre of the epidemic. Curves closely resembling that given by the above equation arise on a number of hypotheses of which two are discussed. First, the organism may be assumed to possess at the beginning of the disease a high degree of infectivity which decreases as the epidemic goes on. If the loss of infectivity is according to geometric law, the normal curve of error already used by Dr. Farr is the result. It is sufficient to state that on various probable hypotheses regarding exposure to infection, etc., the normal curve may be so modified as to take the form found by observation. Secondly, a similar type of curve arises if we consider an epidemic dies out from lack of susceptible persons. It is not possible to distinguish statistically these hypotheses from the consideration of the epidemic form alone. In one case, however, the second hypothesis can be tested. If the form of the epidemic be calculated by assuming different degrees of infectivity on the part of the organism, an infectivity which remains constant during the epidemic, it is found that this curve becomes flatter and flatter the smaller the degree of infectivity. Now, with regard to plague in India among brown and black rats living more or less in the same circumstances, it is observed that many more brown rats are infected than black. In such circumstances the form of the epizootic should be different in the two species if the decline is due to lack of susceptible individuals. As a matter of fact it is nearly identical: a fact which tells strongly in favour of the hypothesis that the epidemic ends because of loss of infectivity on the part of the organisms. This example would be crucial but for the fact that the flea on which the spread of the epizootic depends has a law of seasonal prevalence of its own to which both the epizootics must conform. In many cases, however, the only feasible explanation of the course of an epidemic is that the organism loses the power of infecting as the epidemic proceeds. It is impossible to suppose, for instance, with regard to the great epidemic of smallpox in London in 1901–2 that there were only 8,000 people susceptible, out of a population of 6,000,000. As the course of this epidemic was typical, rising and falling in the manner found to be characteristic, it cannot be argued that the decline was due to the action of the health authorities; all they can have done is to limit the extent of the epidemic, leaving its course unchanged. It is clear, therefore, that in circumstances like this there is some biological factor at work as distinct from a statistical factor. It may then be taken that epidemics in general have a particular form which is identical in many different diseases: plague, influenza, scarlet fever, etc. Even great differences of time do not bring about much change, the form of the epidemic of plague in Sydney in 1900 being nearly identical with that in London in 1665.

The next point requiring consideration is the periodicity in the epidemics of infectious diseases. Taking measles as an example, the common explanation is that each epidemic ends from the exhaustion of the number of susceptible persons, and that it is only when a new population of susceptible children has accumulated that a further outbreak occurs. This explanation fails to account for many of the facts. Even after the very large epidemic of measles in Glasgow in 1906, it was found that nearly half of the children admitted to the fever hospitals immediately thereafter suffering from other diseases had not suffered from measles so that there must have been, with the high infectivity of the epidemic, plenty of susceptible material. The disease subject to the most extensive inquiry hitherto has been measles. Using the method of the periodogram the statistics of London and all the chief towns of the British Isles have been analyzed. It is found that in almost no case is there only one period to be discovered. In London there are several, the chief of which is 97 weeks. This periodicity is found over the whole city. If the application of this mathematical method of analysis be admitted, this coexistence of epidemics of different periods, each appearing at its own time, seems to prove that the termination of an outbreak of the disease is due to loss of infectivity on the part of the organism. Periodicity in other diseases is well known. Thus in the city of Liverpool the epidemics of scarlet fever occurred at regular intervals of four years from 1850–78. On one occasion alone was there an exception when the interval between two epidemics was three years in place of four. A similar periodicity of five years has been observed in Glasgow. There is one specially interesting example, namely the occurrence of plague in Bombay. In many places, such as Hong-Kong, the period between each epidemic is rigidly a year. In such a case the influence of the season of the year seems a sufficient explanation. But the case of Bombay is different. The first epidemic in 1897 had its maximum about the 40th day of the year. From this point until the last year for which statistics are available (1918), the date of the maximum of the epidemic has steadily advanced into the year, advancing about 80 days in 20 years or an average four days a year. It is difficult to account for a phenomenon like this except as being due to some property of the organism. The conclusion must be arrived at that while some periodicities of disease are strictly seasonal, others are not so, and require some further explanation.

A further important application of mathematics to epidemiology has been made by Sir Ronald Ross in his studies on malaria. Here the factors influencing the spread of the disease are numerous. Rainfall and temperature, the number of persons carrying the organism in their blood, and the number of mosquitoes and the proximity of the breeding-places of the mosquito to the abodes of men are all capable of quantitative measurement, and of furnishing guidance in the adoption of suitable administrative measures.

*Climate and Weather.*—The relationship of epidemics to climate has received much attention in recent years, though in many cases the cause of seasonal prevalence is elusive. Thus why scarlet fever should be so regularly an autumnal disease is not at all clear. On many cases, however, much light has been thrown. The discovery, for instance, that malaria was carried by the mosquito elucidates the seasonal distribution of that disease. A temperature of a certain height with associated pools of water is necessary for the rapid development of the mosquito and also a certain degree of temperature for the development of the parasite in the mosquito. In the same way the zone to which

sleeping sickness is limited is a narrow region in which the climate and environment are suitable to the life history of one particular tsetse fly. Much light has been thrown on the epidemiology of plague by the discovery that it was carried to man from the rat by means of the flea. Humidity is necessary for the growth of the flea, and consequently epidemics of plague can hardly occur at seasons of the year when it is warm and dry. Thus the epidemics of plague in Bombay which have advanced progressively later and later into the year now occur when the flea is no longer at its greatest prevalence. With this change the number of cases and deaths has greatly diminished.

The epidemics of summer diarrhoea are also obviously climatic. The organism which causes the epidemic has not yet been discovered, but there is definite evidence that the amount of the disease is very closely associated with the summer temperature. When in London the weekly average of the air temperature rises above 60° F. and remains above that limit a large mortality is the result. Some evidence exists associating the occurrence of the disease with the presence of the house-fly, the fly carrying putrefying organisms from the garbage on which it feeds; but the presence of the fly and of diarrhoea at the same time does not prove that they are cause and effect. Both may well be abundant purely as, or the result of, a coincidence, the climatic conditions favouring both in an almost equal measure. A more difficult problem is the relation of weather to such infective diseases as the pneumonia of childhood. This disease is clearly associated with the winter season of the year but it does not seem specially affected by any special class of weather in that season. In the present state of knowledge it is in those diseases which depend on the spread of the organism by means of parasites that the most close association with weather has been made out.

*Effect of Organisms.*—We now come to the question on the relation of epidemics to the organism which causes them. Why an organism should be capable at one time of causing a great epidemic and at another only a few sporadic cases of a disease has not yet been found out. That organisms do vary in the power of infecting in this manner is a truism to anyone who has administered in the health departments of a large city. At one time the merest contact with a case of smallpox, for instance, will give rise to a large number of cases. At another time a patient suffering from smallpox may even attend in the gallery of a theatre without giving rise to a case of infection.

In recent years, a considerable amount of evidence has accumulated that an organism having found a suitable host or succession of hosts may have its virulence unusually exalted, and if the virulence can be exalted in this manner it is probable that some similar conditions may give rise to a great increase in the power of infection. At any rate, there is no doubt that in certain conditions organisms become highly infective and even the best sanitary precautions exercised in such circumstances can do little more than limit the amount of the disease. But there are further considerations which arise. It would seem as if at times two series of epidemics may coincide and may even mutually influence one another so as to produce a profound joint effect. Thus the great epidemic of influenza in the autumn of 1918 was associated with great activity of other pneumonia-producing organisms, the result being that the death-rate was of extreme amount and was distributed with age in a manner not found in any recent epidemic of influenza.

*Environment.*—While an epidemic may in many cases be chiefly or even wholly due to the active condition of the causal organism it is to be remembered that the vitality and environment of the persons affected must also play a part. Thus, for instance, typhus fever introduced into a crowded slum in which lice are plentiful will almost certainly cause considerable havoc, but even here the havoc will be determined to a certain extent by the season of the year. If the weather be cold the people are crowded together on account of the demand for warmth, and the chance of infection is increased. In addition, in the winter food is often scarce and consequently vitality is low. If on the other hand the invasion of the organism takes place during the summer, a large epidemic will be unlikely. But though these factors act, yet if an organism has an exalted state of activity, an epidemic of the disease may occur at any season of the year, even the most unlikely. Plague, for instance, especially in temperate climates, is essentially a disease of the warmer part of the year, yet it has been known occasionally to occur in large epidemics in the middle of winter, while epidemics of typhus of considerable size have been recorded in the summer time. The great epidemic of influenza in the autumn of 1918 is a marked example, such a season being in the extreme degree a very unusual one for an outbreak of this disease. What part special susceptibility on the part of the population, due to change in vitality, played in this case is not known. Some other influences also act. There is some evidence that fatigue predisposes to enteric fever, an army on the march drinking polluted water tending to have a larger number stricken than a similarly conditioned civil population. Further, it cannot be doubted that the accumulated effect of seasons may tend to depress health and increase susceptibility to certain diseases. The cumulative effect of winter cold may be perhaps traced in children in relation to death from whooping-cough, the average minimum temperature in the winter preceding the maximum number of deaths from whooping-cough by about six weeks, while the form of the two curves is very much the same. The deaths from whooping-cough are due very largely to broncho-pneumonia, yet the seasonal distribution of whooping-cough is not identical with that of the latter disease. Thus scarlet fever, being an autumnal disease and following the hot summer, might in the same way be ascribed to depression produced by continued hot weather, making certain persons more susceptible to the disease. But as scarlet fever is a disease almost absent in warm climates this explanation can hardly be complete, and some other factor must be necessary. None of these questions, however, have at present been sufficiently investigated to allow any dogmatism.

Another point of importance requires special reference, and that is the problem of "carriers," as individuals infected with a disease and cured as regards themselves, but who yet continue to harbour and distribute the parasite, are called. Cholera follows the pilgrims' way, enteric fever the carrier cook, diphtheria the carrier school-teacher.

*References.*—The most important of the epidemiological writings of Hippocrates are the *Epidemics* (Books 1 and 3) and the treatise on *Airs, Waters and Places*, both included in the Sydenham Society's translation (by Francis Adams) and in Littré's text (with French translation). Galen's most important works are *De Febrium Differentiis* and his comments on the Hippocratic *Epidemics* (both in Kuehn's edition with Latin translation). The best edition of Sydenham is that edited for the Sydenham Society by Greenhill. An excellent general account of the progress of knowledge is contained in Haeser's *Lehrbuch der Geschichte der Medizin und der epidemischen Krankheiten*, 3 vols. 3d ed. (1882). English epidemiological history is fully related in Dr. Charles Creighton's *History of Epidemics in Britain*, 2 vols. (1894).

Two papers by Greenwood on the "Epidemiology of Plague in India," *Journal of Hygiene*, vol. x. p. 349 and vol. xi. p. 62, give examples of modern epidemiological method, while his Report "On the Rise, Spread, etc., of Epidemic Diseases," *Internat. Congress of Medicine*, Sec. xviii., London 1913, gives a full study with literature. Two papers by John Brownlee discussing "Theory of Epidemiology in Relation to Plague" (*Proc. Roy. Soc. Med.* 1918, vol. xi., p. 86) and the "Periodicities of Epidemics of Measles" (*Proc. Roy. Soc. Med.* 1919, vol. xii., p. 77) give an account of the statistical and mathematical methods which may be used. Ross's *Prevention of Malaria* and Boyce's *Yellow Fever and its Prevention* discuss theory and practice in all their forms. (J. Bro.; M. G.*)

**EPSTEIN, JACOB** (1880– ), Anglo-Russian sculptor, was born at New York Nov. 10 1880, of Russian-Polish parents. He was educated in Paris and settled in England in 1904. He first came prominently into public notice in 1907, when he received a commission for executing 18 figures to decorate the new buildings of the British Medical Association in the Strand. His work was violently attacked, and led to a prolonged newspaper controversy, and in 1909 he produced designs for the tomb of Oscar Wilde at Père Lachaise, Paris, which considerably shocked French taste. His other work includes the decoration of Church Square, Pretoria, and a number of portrait busts, amongst others those of Lady Gregory and Miss Iris Tree.

**ERITREA** (*see* 9,745).—Surveys made since the settlement of the Danakil frontier with Abyssinia in 1908 gave the colony an area of about 45,800 sq. miles. Proposals made in 1915 that Kassala should be transferred to Eritrea from the Anglo-Egyptian Sudan and Jubuti ceded to the colony by France were not entertained (*see* AFRICA, *History*).

No complete census had been taken up to 1921, when the pop. was roughly estimated at 350,000, including 115,000 Abyssinians. Europeans, apart from soldiers, numbered about 4,000, mostly Italians; next in importance came the Greek community. Asmara (pop. 15,000 including 2,000 Europeans), rebuilt since the Italian occupation, possesses several fine buildings and is the seat of Government; Massawa, the chief port, had some 4,000 inhabitants, including about 400 Europeans and 500 Asiatics (Arabs and Indians). Massawa is in wireless telegraphic communication with the Italian station at Coltano, near Pisa, and with Mukdishu, Italian Somaliland. For local Government purposes Eritrea is divided into eight "commissariats," but certain regions, such as the sultanate of Raheita and other parts of the Danakil country, are not directly controlled by Italy. At the head of the administration is a civil governor, responsible to the Minister for the Colonies.

The chief concern of the authorities in the period 1910–21 was the development of the resources of the country and of the transit trade with northern and central Abyssinia and with the Sudan. Efforts to settle large numbers of Italians in the highlands were abandoned. That region, the only part of Eritrea where Europeans could live permanently, was already largely occupied by Abyssinian agriculturists. While development was hindered by lack of adequate means of transport and the disinclination of Italian capitalists to invest money in the colony (foreign capital was not sought), progress was made. The railway, State owned, from Massawa to Asmara, 75 m. long, was completed in 1912; it rises to 7,700 ft., the altitude of Asmara. A further section of the railway was opened in Dec. 1914, and in 1915 a loan of £800,000 to be spread over five years was authorized by the Italian Treasury to complete the line via Keren to Agordat—184 m. from Massawa and on the main caravan route to Kassala. The route to Adowa (Adua), N. Abyssinia, was improved, and from the port of Assab, on the Danakil coast, a good road was built to the frontier at Ela, whence a caravan route goes to central Abyssinia.

The Asmara-Agordat railway opened up the Khor Baraka district, where the cultivation of cotton was successfully undertaken by an Italian company. Cotton was also grown in the river Gash (Mareb) area and irrigation work began in 1915. It was estimated that 140,000 ac. were suitable for cotton-growing. Ginning mills were erected at Agordat and Massawa.

An industry which made considerable progress was that in vegetable ivory—the collection of nuts from the dum palm, which grows on the banks of the Baraka, the lower Mareb and other regions. The exports rose in 1917 to 10,000 tons, valued at over 1,000,000 lire. Salt deposits were worked in the neighbourhood of Massawa and in the Danakil country. In 1917–8 a Decauville line was built from Fatima harbour, 76 m. S. of Massawa, to serve the Dalol potash mine, which lies 16 m. within the Abyssinian border. The Decauville line, 46 m. long, stopped at the frontier. Stock-raising remained, however, the principal occupation of the people, and skins and hides the most valuable export. Salt, dum nuts and mother-of-pearl are the chief other exports. Cotton goods and dura (Indian millet) are the chief imports. The value of imports at Massawa rose from 17,160,000 lire in 1911 to 47,591,000 in 1917, and was 103,811,000 lire in 1918 (the result of inflated prices). Exports increased from 8,818,000 lire in 1911 to 21,660,000 in 1917 and were valued at 85,254,000 in 1918. The value of transit trade was returned at 3,351,000 lire in 1911, 5,845,000 lire in 1915, 2,498,000 lire in 1917 and 5,415,000 lire in 1918. Many of the goods classed as exports of the colony were however reexports from Abyssinia or the Sudan. The value of the internal trade with Abyssinia was unascertained, that with the Sudan reached a value of about £100,000 in 1918–9. Oversea trade is mainly with Italy, Aden and India. The shipping which entered Massawa in 1911 had a total tonnage of 206,000, in 1915 the tonnage was 356,000, in 1918 it had fallen to 103,000 tons.

There was (1919) a military force 12,000 strong (3,000 Europeans, 9,000 Abyssinians). Eritrea also supplied battalions for Tripoli, Cyrenaica, and Italian Somaliland. Eritrean troops served with distinction in the hostilities in Tripoli, 1911–4, and in the World War.

Up to 1921 Eritrea had not become self-supporting, though between 1915 and 1920 revenue raised in the colony doubled. For 1920–1 ordinary revenue was estimated at 20,122,000 lire, civil expenditure at 12,049,000 lire and military expenditure at 3,847,000 lire. The Italian Treasury made a grant of 6,650,660 lire. Signor (afterwards Marquis) G. Cerrina Feroni, who had served in the colony for several years, was in 1919 appointed governor.

See Tommaso Tittoni, *Italy's Foreign and Colonial Policy* (English trans. 1914); *Eritrea*, a British official handbook, with bibliography (1920); the *Rivista Coloniale* and the *Bollettino* of the Italian Geographical Society. (F. R. C.)

**ERNLE, ROWLAND EDMUND PROTHERO, 1ST BARON** (1852– ), British agriculturist and politician, was born at Clifton-on-Teme Sept. 6 1852, the third son of the Rev. Canon Prothero, rector of Whippingham, Isle of Wight. He was educated at Marlborough and Balliol College, Oxford, where he took his degree in 1875, subsequently being elected to an All Souls fellowship. He remained at Oxford for some years as a fellow and tutor, and became well known as an authority upon agriculture. From 1883 to 1884 he was university proctor, and in 1894 became editor of the *Quarterly Review*, retaining this post till 1899. In 1898 Mr. Prothero became chief agent to the Duke of Bedford, and in this capacity his experience on agricultural questions was much extended. In 1910 he unsuccessfully contested the Biggleswade division of Beds. as a Unionist. In 1913 he was a member of the royal commission on railways, and in 1914 was elected member for Oxford University. He sat on the departmental committees on the home production of food (1914) and the increased price of commodities (1915), and in 1916, on the formation of Mr. Lloyd George's Government, became president of the Board of Agriculture. He resigned his office in 1919 and was raised to the peerage. Lord Ernle published *Pioneers and Progress of English Farming* (1887), and *English Farming, Past and Present* (1912); besides the *Life and Correspondence of Dean Stanley* (1893); *Letters of Edward Gibbon* (1896); a *Memoir* of Prince Henry of Battenberg (privately printed, 1897); *Letters and Journals of Lord Byron* (1898–1901) and *Letters of Richard Ford* (1905). His *Psalms in Human Life* (1903; enlarged 1913), tracing the influence of the Psalter on the notable men of succeeding generations, had a great popular success.

**ERZBERGER, MATTHIAS** (1875–1921), German politician, was born Sept. 20 1875 at Buttenhausen in Württemberg. He began life as a national school-teacher and in 1896 became a member of the staff of the *Deutsches Volksblatt*, at Stuttgart. In 1903 he was elected as a representative of the Catholic Centre party in the Reichstag, and soon, by virtue of his unusually varied activities, took a leading position in the parliamentary party. He occupied himself in particular with colonial questions. During the World War, although he had at first put forward in letters to leading military authorities, since published, extravagant plans for the German annexations, he soon became a most active agent in attempts to draw the Allies into negotiations for peace. He was the real author of the so-called Peace Resolutions adopted by the Reichstag July 17 1917. He likewise employed his relations with the Austrian Imperial Court in order to work for an early conclusion of peace. In Oct. 1918 he entered the Government as a Secretary of State after he had contributed to bring about the fall of Bethmann-Hollweg. Entrusted with the task of conducting the negotiations for the conclusion of the Armistice, he signed (Nov. 1918) the Armistice agreement in the saloon railway carriage of Marshal Foch in the Forest of Compiègne. After the elections for the National Assembly he entered the new Government of the German Republic in Aug. 1919 and was appointed Finance Minister of the Reich. In the National Assembly he succeeded in forcing through the new measures of taxation, notwithstanding the vigorous attacks made upon him by the Right. He set himself in particularly sharp opposition to the German National party (the old Conservatives), on whom he laid the responsibility for the World War; the result was a personal dispute with the leader of the Nationalists, the former Secretary of State for the Treasury, Dr. Helfferich, and Erzberger was ultimately compelled to bring an action against Dr. Helfferich for slander. The action resulted in Helfferich's being condemned to pay a small fine (the German law does not admit of any damages or penalties for slander);

the court, however, in its judgment took the line that Helfferich's allegations regarding Erzberger's corrupt business practices and untruthful statements on the part of Erzberger were justified. Erzberger was consequently compelled by his party to resign his ministerial office. During the case an attempt was made upon his life as he was leaving the court by a youth who had been brought up under reactionary influences. He was rather seriously wounded by the bullet from the assassin's pistol. Erzberger was once more returned to the Reichstag at the general election of Jan. 1920, but in accordance with the wish of his party abstained from immediate participation in politics, as proceedings had been instituted against him on a charge of evading taxation. In 1920 he published a memorandum endeavouring to justify his policy during the war, and he followed it with interesting disclosures regarding the attitude of the Vatican in 1917 and the mission of the papal legate in Munich, Pacelli, to Berlin. Erzberger's power in German politics was based upon his great influence with the Catholic working classes in the Rhineland and Westphalia, in central Germany and in Silesia. In the industrial regions of these districts the Catholic workmen were organized in their own trade unions on lines of very advanced social policy, and Erzberger became the leading exponent of their views in the Reichstag and on public platforms. On the other hand, he incurred the strong opposition of the conservative and landed section of the Catholics, of some of the higher clergy like Cardinal Archbishop Hartmann of Cologne (d. 1919) and of the Bavarian agricultural interest as represented by the Bavarian Catholic People's party in the Diet at Munich and in the Reichstag in Berlin. Erzberger continued to be pursued by the relentless animosity of the reactionary parties, the Conservatives (now called *Deutsch-Nationalen*) and the National Liberals (now styling themselves the *Deutsche Volkspartei*). This hostility, which amounted to a real vendetta, was based, not so much upon the foreign policy of its victim, his negotiation of the Armistice terms and the decisive influence which he exercised in securing the acceptance of the Treaty of Versailles, as upon his financial policy both as Finance Minister in 1919 and as the Democratic Catholic supporter and, it is said, the political adviser of the Catholic Chancellor of the Reich, Dr. Wirth, in the preparation in the summer of 1921 of a fresh scheme of taxation designed to impose new burdens upon capital and upon the prosperous landed interest. The denunciations of the Conservative and National Liberal press undoubtedly went beyond the ordinary limits of party polemics. Thus the *Tägliche Rundschau* observed, in allusion to Erzberger's personal appearance, "he may be as round as a bullet, but he is not bullet-proof." The climax of these attacks was that Erzberger was assassinated on Aug. 26 1921 while taking a walk with a parliamentary colleague in a lonely part of the Black Forest near Griesbach. The assassins, two well-dressed young men, were very generally believed to have been at least voluntary agents of the reactionary and military cliques. The assassination caused great political excitement, and exacerbated existing party feuds.

(C. K.*; G. S.)

**ESHER, REGINALD BALIOL BRETT,** 2ND VISCOUNT (1852– ), English politician and writer, eldest son of the 1st Viscount Esher (*see* 9.768), was born in London June 30 1852. He was educated at Eton and Trinity College, Cambridge, and afterwards entered politics, becoming private secretary to the Marquess of Hartington in 1878. From 1880 to 1885 he sat as Liberal member for Penrhyn and Falmouth, and in the latter year unsuccessfully contested Plymouth. From 1895 to 1902 he was secretary to the Office of Works. He succeeded his father in 1899 and in 1901 was appointed deputy constable and lieutenant-governor of Windsor Castle. In 1902 he was appointed one of the commissioners who inquired into the conduct of the S. African War, in 1903 he was chairman of the War Office Reconstitution Committee, and in 1905 became a permanent member of the Committee of Imperial Defence. From 1909 to 1913 he was chairman of the Territorial Force Association of the county of Middlesex. Lord Esher was selected by King Edward VII. as one of the editors of the *Letters of Queen Victoria*, which appeared in 1907, and he produced *The Girlhood of Queen Victoria* (1912). His other works include *Footprints of Statesmen* (1892); *To-day and To-morrow* (1910); *The Influence of King Edward* (1914); *After the War* (1918); and *The Tragedy of Kitchener* (1921).

**ESMEIN, JEAN PAUL HIPPOLYTE EMMANUEL ADHÉMAR** (1848–1913), French jurist, was born at Tourvérac, Charente, Feb. 1 1848. In 1888 he became professor of law in the university of Paris, and in 1904 member of the Institute of France. His best-known works are *Cours élémentaire d'histoire du droit français* (1895) and *Éléments de droit constitutionnel français et comparé* (1903). He died July 22 1913.

**ESSAD** (*c.* 1875–1920), Turkish pasha and Albanian leader, sprang from the rich Albanian family of the Toptani, and was born at Elbasan. In his youth he sought and obtained the favour of 'Abdul Hamid. He entered the political service of the Sultan, enriched himself therein, and, as was then usual, became a pasha while still a young man. In Elbasan he played the leading political part. When the Turkish Revolution broke out, Essad quickly bent his steps to the new path, which seemed to him the most promising, and was deputy for Albania in the first Turkish Parliament. His influence over the somewhat uncertain Albanian population, and the desire of the Constantinople Government not to have so exceedingly cunning and skilful a man for their enemy, led to his being in 1912 given the high command at Scutari, then under siege by the Montenegrins, though he knew almost nothing of military matters. Indeed, he never showed himself to the troops except once, in March 1913, when he had 50 men shot for an insignificant revolt. Political antagonisms and personal motives combined to make the town commandant, Hasan Riza, the target of his hatred. This honourable Old Turk was the soul of the defence of Scutari; and, in order to have a free hand for his own secret dealings with the Montenegrins, Essad had him assassinated on Jan. 13 1913. On April 25 Essad took the lead in the unreal and theatrical ceremony of handing over the fortress to Montenegro, but when the princedom of Albania was constituted after the Balkan War, Essad became Minister of War and also Minister of the Interior to William of Wied, and brought his policy into close touch with that of Italy. During the World War he was president of the Albanian delegation in Paris but appeared at frequent intervals at Salonika and on the Albanian front as a guerrilla leader. He succeeded in bringing about the overthrow, by a so-called National Assembly in Cusonio, of the "Provisional Government of Durazzo" which was under Italian influence, and this National Assembly purposed to proclaim Essad King of Albania. But on June 13 1920 he was killed in front of the Hotel Continental in Paris by Aveni Rustam, an Albanian.

(F. C. E.)

**ESTHONIA** (Eesti) was declared an independent republic on May 19 1919. The former Russian province of Esthonia (*see* 9.797) was extended by the Russian law of April 12 1917 over the four northern districts of Livonia, inhabited by Esthonians, namely Pernau (Parnu), Fellin (Viljandi), Dorpat (Tartu, russ. Youriev) and Verro, and the island of Ösel or Ezel (Saaremaa). The Russo-Esthonian peace treaty of Feb. 2 1920 added Narva, parts of the Yamburg and Gdov districts of the province of Petrograd and of the district of Pechori (Petserimaa) of the province of Pskov. This new strategic frontier runs from 10 m. E. of the Narova river across the Peipus lake towards Isborsk. The western frontier bordering Latvia includes the town of Valk ceded to Esthonia by arbitration on ethnographical grounds, and runs in the same direction towards the Baltic Sea. Thus Esthonia's political boundaries coincide almost completely with the linguistic extension of the race. The area, 18,300 sq. m., is larger than Switzerland, Denmark or Holland.

The population of the former province of Esthonia was estimated in Jan. 1913 at 492,000; United Esthonia, as the republic is called, has a pop. of 1,500,000 (according to Martna 1,750,000). About 90% of the pop. belong to the Esthonian race, 4% to the Russian and 2·4% to the German Balto-Saxons (called Balts, Germano-Balts, in Esthonia "Saksa," who formerly numbered 22,800, 4,700 forming the nobility, 300 the clergy). There were in Dec. 1920 about 40,000 resident foreigners, chiefly Russians

Until 1918 the Balts were economically preponderant both in town and country. To this class belonged most of the owners of the big estates ("Baltic barons"), the commercial magnates and the chief traders and merchants in the larger towns, but great changes have since taken place. During 1897–1900 the average annual rate of increase showed a slow growth of pop., 9·3 per 1,000 in Esthonia and 8·0 in Livonia. About 300,000 Esthonians are colonists in Russia and Siberia, having emigrated chiefly because of the economic dependence of the landless agricultural population. Before the war the birth-rate averaged 28, the death-rate 20 per 1,000. The predominant religion is Protestant, with a small number of Greek Orthodox Christians.

About 74% of the pop. is rural, 60% being engaged in agriculture. This rural pop. was formerly divided into three main groups of which the first has been suppressed, (*a*) large landowners with 829 estates, (*b*) peasant-proprietors, a middle class (nicknamed the "grey barons") owning 50,961 holdings, and (*c*) the tenants of small allotments and agricultural labourers forming about three-quarters of the rural pop., whom it was proposed to settle partly on the estates nationalized by the State. The economic consequences of this social dislocation were in 1921 the problem of the day, but the race and class hatred were so strong that these difficulties were disregarded.

The figures for 1919 supplied by the Ministry of Labour showed a decrease of workers engaged in industry; 271 private concerns employed 15,417 workers (printing works and large business concerns are included); the Government employed 21,006 persons (on railways, post and telegraphs, harbour works, timber industry). Of the private industries the more important were: cotton, 3,007 workers; yarn and wool, 2,000; flax, hemp and rope, 1,200; paper, 1,232; metal and shipbuilding, 3,700; cement and bricks, 625; tanneries, refineries and soap, 345; food production in steam mills, starch, etc. 612; chemical (matches, gas), 820. Before the war the cotton mill at Kraenholm near Narva with 600,000 spindles had 12,000 workers, in 1920 only 2,700; of capital invested, 45% was Russian, 30% English and 25% German. Want of fuel and raw material stopped work in flax spinneries, cloth works and leather factories. In 1921 the Russo-British shipyard was trying to sell its floating dock; a new company was initiating the sugar industry and an English firm was promoting the mechanical treatment of flax. Foreign capital was wanted for industry as well as for the revival of agriculture. The coöperative system takes a large share in public educational work (theatres, libraries, museum, literary society). The figures for 1917 were: 99 societies of mutual credit with 42,606 shareholders; 98 coöperative supply stores with 15,052 members; 12 agricultural coöperative societies with 2,018 members; 138 coöperative milk societies. A wholesale coöperative society is preparing for large activities in timber, flax, fish, vegetables and manufactured goods. Before the war Esthonia and northern Livonia were almost self-supporting in regard to foodstuffs. Wheat for the towns and sugar were supplied from Russia, while dairy products, pigs, potatoes (spirits) were exported. It is impossible to estimate separately the losses from war, revolution, military occupation and the suppression of the large estates. The figures available are conflicting. Statistics published by the Ministry of Agriculture showed that the area of arable land and agricultural production in 1920 were approximately the same as in 1916, while critics advanced totally different figures, and professional circles and influential parties like the Maaliit, formerly led by K. Paetz, complained of the ruinous influence of socialistic doctrines on economic policy. As in the other border-states, the large number of government officials and their corrupt methods were subjects of frequent discussion in the daily press. There seemed no doubt that the productive capacity of the country had been at least temporarily reduced.

*Natural Resources.*—The republic in 1921 owned 1,170,000 ac. of coniferous woods and 650,000 ac. of leafy or mixed woods. Over 90% of this area, forming 79·2% of the large estates, was nationalized with the latter and is managed by the State. Together with the concessions in Russia granted by the Peace Treaty these are expected to rank as assets. Extensive deforesting in the course of the war for fuel and for military purposes made serious inroads upon the forest area. The local need of fuel has rendered exportation on a large scale impossible. Concessions of combustible shale to a British-Belgian company were in prospect in 1921. There is a cement factory at Port Kunda. Near Isborsk are concessions of plaster of Paris and at Suurup of limestone. Peat occurs in the Yupre district. The Narova rapids are expected to develop 600,000 H.P. By Art. 33 of the Land Act of Oct. 10 1919 all natural resources of the soil are property of the republic.

Except Baltic Port, which is to be declared a free port, all Esthonian seaports are icebound for some time of the year. The port of Revel (Tallinn)—depth 23–30 ft., length of quay 10,004 ft., capacity of tonnage 55,000, warehouse area 1,335,005 sq. ft.—is the most important. The total quay length of the Esthonian harbours (Revel, Pernau, Narva, Port Baltic, Hapsal, Arensburg, Kunda, Lohsa, Rohukula) is about 50,000 ft., and shipping of a total tonnage of 145,000 can be berthed. Special harbour dues, 4d. per each gross registered ton. For the first half of 1920 the shipping which entered Revel was 709 Esthonian ships, net tonnage 27,886; 29 German, net tonnage 18,653; 107 Finnish, 16,860 tons; 47 Swedish, 10,001 tons; Danish, 6,882 tons; 2 American, 5,055 tons; 1 French, 1,190 tons; British none. Total shipping 948 with 91,324 net tonnage. In 1913 590 steamships entered Revel with a tonnage of 477,154. Of these 192 were German, 149,362 tons; 132 Russian, 91,361 tons; 70 British, 78,138 tons.

Imports and exports for 1920 amounted, according to the Government returns, to 3,912,394 and 7,675,508 tons respectively; the total value for the second half of 1920 in Esthonian marks (based upon the rate of exchange £1 = E.mk. 270) was 703 millions for the imports, 738 millions for the exports and 961 millions for goods in transit. Nevertheless Esthonia suffered from an adverse exchange. In March 1920 £1 = 350 E.mk., in May 1920 = 240, in May 1921 = 1,075. Imported goods were beyond the purchasing power of the population. The prosperity of the Baltic states is based chiefly on internal trade and foreign trade with Russia. For 1920 Esthonia received from Great Britain coal, petroleum, cotton and sugar, 1,142,759 tons, exporting to her 3,531,362 tons of timber, paper, pulp, etc. Germany exported to Esthonia 1,298,670 tons of salt, iron goods, and fertilizers, and received 275,905 tons of potatoes. Imports from other countries were miscellaneous and of minor importance. Esthonia exported in 1920 potatoes, spirits, timber, pulp, paper, flax, bricks and cement, and imported flour, sugar, herrings, salted fish, salt, leather, wool, cotton, iron, agricultural machinery, coal, petrol, fertilizers.

After the German occupation, when the Russian frontier was closed, the factories worked with a minimum production, having no markets; stocks of raw material became short and all factories were cut off from their financial bases because the Revel banks, which were obliged to keep nearly all their deposits in Russia, were practically bankrupt. With the financial help of the German military authorities, the factories worked for Germany and the Ukraine, but most goods were put into stock. The first provisional Government did much to promote industry; later, however, the Central Professional Union of Workers exercised a deleterious influence.

*Origin of the Esthonian Republic.*—The declaration of independence of May 19 1919 stated that "no material improvement had been effected by the Russian revolution in 1917," that later "Esthonia was sacrificed to Germany under the Brest-Litovsk Treaty"; that in Nov. 1918 "the Soviet armies attacked her, bringing in their train more suffering and misery"; and that "in consideration of this the Esthonian nation was under no obligation to respect the union with Russia." After the fall of Tsardom the Esthonians feared anarchy more than Russification, but after the defeat of Russia it was German preponderance which they chiefly dreaded. They were thus virtually compelled to declare for independence. On April 12 1917 the Russian provisional Government accorded the enlarged Esthonian province a representative body (Diet, "Maapäev" or "Maanoukogu") and the right to recall all their nationals from the Russian colours with a view to the formation of a national defence force. On July 1 and Nov. 15 1918 the Diet declared its independence and rejected the proffered aid of Germany. With the exception of their Bolshevik section, all Esthonian political parties under the leadership of K. Paetz and others based their policy on the defeat of Germany, although that country's power was still unbroken. The Balte-Saxons, on the contrary, especially the majority of the gentry, released from the allegiance to the throne, which to most of them meant the Russian State, decided to turn to Germany for help. Their disbelief in the creative power of the Esthonian people at that moment was all the more to be excused, seeing that the capital was under the rule of Esthonian Bolsheviks, whose leader, Anwelt, was openly preparing a reign of red terror. The marshal of the nobility, Baron Dellingshausen, on Jan. 28 1918 invited the Germans to occupy Esthonia; they took Revel on Feb. 25. Over a hundred hostages were taken by the retiring Bolsheviks; of these Dellingshausen was to be tried in Petrograd, whilst the majority were transported under ghastly conditions to Siberia; through the intervention of Germany they were, however, repatriated. On Feb. 24 an Esthonian provisional Government was formed (Paetz, Wilms, Poska, Larko, Kukk and others) and an independent republic proclaimed. Germany did not recognize this Government, but established a régime of military occupation under which the Balts were made dominant; this lasted over eight months. The German occupation widened the gulf between class and race and postponed the formation of an Esthonian force hostile to Germany. Still the power of the local Bol-

sheviks was broken, many lives were saved and thousands of Esthonians effected their escape from Soviet Russia. England, France and Italy, informed of the views of Esthonia, expressed in May their readiness to grant provisional recognition to the Esthonian National Council as a *de facto* independent body (Prize case of the ss. "Kayak," Admiralty Court of Appeal, Jan.–Feb. 1919), while the German Emperor was considering the request initiated by the Baltic nobility (April 13) for annexation by Germany. There could hardly have been a greater contrast between the two sections of the Esthonian population. The Nov. Armistice contained a clause compelling the Germans to maintain order and law in the occupied territories of Russia, while neither the Allies nor the local governments which came into being had sufficient forces available to resist the advance of the Russian red forces and the rising of the local pro-Bolsheviks. Even then the Esthonian National Council insisted upon taking over all responsibility; on Nov. 14 the German representative, the Social-Democrat deputy Winnig, resigned in their favour. On Nov. 19 an evacuation agreement was signed, which, however, had not the expected effect of leaving the Esthonians in possession of the military stores, etc. All that was available for the defence of the country were two units, some 600 men strong, under Col. Weiss, of Baltic volunteers (the Baltic regiment), including 18 barons, Stackelberg in the ranks, prepared to assist in combating Bolshevism. At first Gen. Laidoner, later knighted by the King, had at his disposal this intrepid corps, besides 3,000 volunteers from Finland under Gen. Wetzer, enlisted by means of a loan of 20 million mks. guaranteed by the Revel banks. The Esthonian units in process of formation were at that moment keener against the retiring Germans than against the Bolsheviks.

*The War against Soviet Russia* (Nov. 1919 to Feb. 2 1920).—The Russian red army—nominally Esthonian Communists—invaded Esthonia as the German troops retired. For some weeks three-fourths of Esthonia experienced the full measure of Bolshevik methods. The cruelties and massacres at Dorpat (liberated Jan. 14 1919), Narva, Vesenberg, etc., produced an anti-Bolshevik feeling among the Esthonian soldiery. A Finnish loan and war material from Great Britain helped to arrest the enemy's advance 30 m. from Revel, and the Bolsheviks were driven out of the country in the course of a month. But fresh forces were threatened—Latvia having become Bolshevik—all along the 300 m. of land frontier. With the help of the British navy, which in Dec. prevented the Bolshevik fleet from taking Revel, it again became possible in May to land forces in the rear of the enemy (Luga river) in coöperation with Russian anti-Bolshevik forces, a coöperation which tended to grow less close towards the autumn. The commanding town of Pskov was taken when an unexpected incident threatening a new German danger necessitated military operations in the direction of Riga. This town (*see* LATVIA) had on May 22 been liberated by a daring raid in which a decisive part was played by the Baltic Landeswehr under the command of a German, Major Fletcher, one-third of which consisted of volunteers from Germany. The advance of this force northwards conflicted with the views of the Entente powers. The Esthonians detached troops and armoured trains to this new front. Fighting began near Venden (June 2), an armistice declared on June 11 was broken, and fighting continued near Rup (June 13), followed by a victorious advance towards Riga. According to the terms of the armistice of July 3, drawn up by Gen. Sir H. Gough, while the Baltic section obtained an English commander, Col. A. R. Alexander, the purely German section of the opponents had to evacuate Riga, where the Latvian Government of Ulmanis was reëstablished. Esthonia received the thanks of the Lettish National Assembly for the liberation of northern Latvia, and an agreement for mutual help—the nucleus of a Baltic federation—was signed on July 20. Another incident described as "a German conspiracy against Latvia" diverted the Esthonian forces from the Bolshevik front—the Bermondt affair; an arrangement made by Gen. Marsh in July for a combined advance in Sept., with the help of Bermondt's Russo-German volunteer force, was cancelled at the instance of Latvia, and the Esthonians had again to assist Latvia. Meanwhile, in order to divide their enemies, the Soviet Government offered peace to Esthonia. The North-Western Government retorted by recognizing Esthonia's independence (Aug. 11). A sum of $50,000,000 was advanced by the United States (Aug. 15), Russian vessels were sunk by the English in the Kronstadt harbour, and the Esthonians continued to assist—though half-heartedly—the ineffective offensive against Petrograd in Oct. After Sept. 12, in accordance with a vote of the Constituent Assembly, the Esthonians prepared the ground in Latvia, Lithuania and Finland for peace negotiations with Russia. (The Dorpat Conferences, Sept. 29–Oct. 1, and Nov. 9, further developed the idea of a Baltic federation.) On Nov. 20 Gen. Yudenich handed over the command to Gen. Laidoner, and on Nov. 26 terminated his military operations. The Soviet army was stopped at Narva (Nov. 22) and the Russian white army sought refuge in Esthonia. On Dec. 1 peace pourparlers were resumed. On Dec. 4 hostages were exchanged as provided in the armistice signed at Dorpat (Dec. 3). After extensive negotiations (Krassin, later Joffe, for the Soviet Power, J. Poska for Esthonia) a treaty of peace was signed on Feb. 2 1920, and approved by the London declaration of Feb. 24. The chief stipulations of this treaty provided for the suppression of all armed vessels on the Peipus lake; Russia declared herself prepared to join in any future recognition of the international neutrality of Esthonia; foreign troops were to be demobilized (Russian white army); Russian State property devolved to Esthonia, Russia to pay 15,000,000 gold rubles (about £1,500,000) while Esthonia was not to be held responsible for Russia's debts (this was counter to the French point of view); Russia was to return all property removed from Esthonia; Esthonia to have the preferential right to build a railway from Revel to Moscow; a timber concession for 2,600,000 ac.; a favoured-nation clause and the fixing of a strategic frontier and ethnographic boundaries in the Pechora district were included. Russia obtained the concession that transit freights should in no case exceed the local charges and that no import and transit duties should be levied by Esthonia; further she obtained preferential rights to the electric power from the Narova waterfalls. Russia, anxious to extend her outlet towards the West, offered similar advantages to Latvia, Lithuania, Finland, the Ukraine, Georgia and Poland, thus creating a new situation in Eastern Europe. Esthonia was the first to become the continental market of exchange for the trade between Western Europe and Russia (under Gukovsky, chief of the Soviet trade delegation at Revel, which became a centre of speculation).

Esthonian policy before and after the peace was in close touch with Great Britain (missions of Gen. Gough, Gen. Talent, Col. Percy Gordon) and the United States (Col. Green, Prof. Morrison). Esthonia received from these countries respectively military, financial and medical aid (*e.g.* against typhoid imported by Russian refugees), as well as moral support in consolidating her independence and in coping with the preponderance of the gentry, the pro-German or pro-Russian reactionary barons. The problem involved in the land question deserves special attention, being typical of the changes initiated in all the border states (Latvia, Lithuania, Poland, Rumanian Bessarabia and Georgia), which adopted the system of appropriation by the State of all large agricultural estates without adequate compensation, the management of forests by the State, and the sub-division of arable land into small holdings (decrees of Dec. 17 and Feb. 28 1918, the Land Act of Oct. 10 1919). A Constituent Assembly was convened after the liberation of the territory on April 28.

The 120 members were divided into three leading parties: (*a*) Democrats or Peasant party, a bourgeois party—leader Paetz; (*b*) Labour party, socialists—leader Strandmann, later prime minister, promoter of the agrarian reform; (*c*) Moderate Social Democrats and Social Revolutionaries. A provisional constitutional charter was framed on June 6 1919 and definitely adopted in an amended form on June 15 1920 (translated into English, *Baltic Review*, L., vol. i., Nos. 2 and 3). The power of the State was declared to be "in the hands of the people"; Esthonian was to be the official language. Every Esthonian citizen was given the right to determine his own nationality, the members of minority nationalities being entitled to form corresponding autonomous institutions; where the majority of the inhabitants were not Esthonians the local language was

recognized as the official language (this applied chiefly to Swedish, Russian and German). The people exercise their political rights (*a*) by plebiscite, (*b*) by their initiative in legislation, and (*c*) by election to the State Assembly (Riigikogu). No law passed by this Assembly can come into force if opposed by one-third of the legal number of members pending a plebiscite. The State Assembly is composed of 100 members elected for three years by universal suffrage. The governor, *i.e.* the head of the State (Riigiwanem or State Elder), acts as prime minister. The other ministers are elected by the Assembly. They must resign on failure to obtain a vote of confidence. The State Court of Justice is elected in the same way, and selects the local judges for life.

The Church is separated from the State, all glebe land and incomes based upon former public law being abolished without compensation by the Land Act. The Minister for Foreign Affairs, J. Poska (d. 1920), supported by the Constituent Assembly, negotiated the peace with Soviet Russia and prepared the *de jure* recognition of Esthonia. The decision of the Supreme Council at Paris on this matter (Jan. 21 1921) was not adopted by the United States. Admission to the League of Nations was refused on Dec. 17 1920 owing to the attitude of the French and British delegates.

The Constituent Assembly dissolved itself on Dec. 21 1920. The State Assembly began its functions on Jan. 4 1921. Labour (22 seats) and Social Democrats including Communists (34) formed the majority; the remainder (44 seats) belonged to the Peasants' party, Christian, popular party and national minorities. The Cabinet was a Coalition; premier, K. Paetz. Its programme reflected the problems and tendencies of the day: (1) Estates to be divided into small holdings; (2) enforcement of Land Act to harmonize with the food problem; (3) estates managed by State officials to be either let or divided; (4) suitable buildings on estates to be arranged for industry; (5) consolidation of internal peace; (6) de-control; (7) organization of minorities; (8) religion to be taught in the schools if so desired; (9) *emigrés* to be repatriated; (10) compensation for nationalized land to be reëxamined.

At the municipal elections the Social Democrats lost a number of seats, but on the other hand Communistic plots were sporadically referred to in the press.

*The Land Problem.*—The division of property before the Land Act of Oct. 1919, according to official figures for United Esthonia, with the exclusion of the Pechori district, was as follows:—

| | | Total acreage. | Av. incl'd'g waste land. |
|---|---|---|---|
| (A) Large Estates | | | |
| (*a*) belonging to individual owners | | | |
| 734 manorial estates (knights' estates) | | 3,791,718 | 5·165 |
| 95 entailed estates (110) | | 998,133 | 10·507 |
| 61 small estates | | 74,456 | 1·286 |
| 890 | | 4,864,307 | |
| (*b*) belonging to corporations | | | |
| 8 to the nobility corporations | | 109,712 | 13·714 |
| 101 to the Russian State | | 851,945 | 8·534 |
| 19 to the Peasant Land Bank | | 168,575 | 8·872 |
| 3 charitable endowments | | 20,477 | 6·825 |
| 108 Church estates (glebe land) | | 133,796 | 1·239 |
| 18 to townships (corporations) | | 102,376 | 5·688 |
| 257 | | 1,386,881 | |
| | Total | 6,251,188 | |
| (B) Small Holdings | | | |
| 23,023 leased farms on large estates | | 1,375,329 | 59·73 |
| 50,961 farms owned by the occupiers | | 4,349,614 | 84·76 |
| | | 5,724,943 | |

Of the large estates 79% (84%) was forest and 1,386,881 ac. agricultural land. Hardly 1% of the small holdings is under forest, while 4,927,763 ac. are agricultural land.

This division of property, large and small farming being conducted in independent self-contained units, proved economically progressive. (Only some 12,000 leasehold farms in North Esthonia were too small.) But social and political conditions as well as racial antagonism produced a change tantamount to a social revolution, accomplished by a coalition of the petty bourgeoisie and the proletariat with a speed attributed to the danger of a spontaneous Bolshevik move. The beginning was made by the decree of Dec. 17 1918 empowering the State to take possession of "badly managed" estates. This was not a corn production act, nor a means of enforcing proper cultivation; no notice was served, no directions given to the landlord, no default established, no arbitration admitted, no compensations. The economic result was negative (as shown by the Agricultural Conference Nov. 1918), but the measure satisfied some aspirations, seeing that in the course of a year some 300 landlords were dispossessed. On Feb. 26 1919 another decree promised the division of the large estates among the soldiers and the landless agricultural workers, and on Oct. 10 of the same year an agrarian reform was passed by the Constituent Assembly. It was based on the assumptions that the rights of the landlord were non-existent in the cases (*a*) of entails, (*b*) of glebe land, (*c*) of estates seized by Sweden after 1680 and restored to their owners by Russia according to Art. XL of the Nystad Treaty of 1731 (this applied to ⅔ of the manorial estates) and (*d*) with regard to former waste land (peasant land) reunited to the demesne according to the Statutes of 1849 and 1856 (about ⅓ of this category of land). No compensation was therefore to be granted in these cases. The fact that during the German occupation the landlords were prepared to cede ⅓ of their land for German colonization, and the desire to prevent confiscation without order and programme as in Russia, were also of moment.

According to the Act of Oct. 10 the nationalized land fund had to be redivided on the following lines: (*a*) Leased farms remained the property of the occupier; (*b*) forests were to be managed by the State (Art. XXVI.); (*c*) the manorial houses, gardens and parks became the property of the State (Art. XXVII.); (*d*) glebe land must either be let to church parishes or distributed to neighbouring boroughs; (*e*) arable land was to be allotted in small holdings to soldiers, their relatives and landless workers, with hereditary tenure. The former owners were to move from their homes, only foreigners to remain in occupation of their lands and homes, until a definite compensation Act could be passed and the indemnity paid. The principles on which compensation was to be calculated were laid down in the Act (Art. XII.–XIV.) and, unless alterations should be introduced, would lead to the following consequences.

The valuation of the land for the former land tax was to be the limit of the indemnity. Therefore (*a*) many mortgagees, banks as well as private persons, would lose their security, although since 1864 all such charges had been duly registered. In Northern Esthonia mortgages of 34,352,400 rubles would be deprived of security to the mortgagees. (*b*) The value of the buildings alone was insured against fire in 449 estates for a sum of 42,544,264 rubles, while the proposed amount of compensation for 468 estates amounted to 11,981,450 rubles. (*c*) In numerous estates the value of drainages effected for the last 25 years is higher than the promised compensation for the land. (*d*) The rate of indemnity for live stock and implements was from 15 to 150 times lower than their market value. Even Esthonian politicians (Toennison) appeared doubtful whether the ruin of the landlords would prove ultimately of economic benefit to the country, and amendments were being discussed in order to restore confidence and improve the money market. The Ministry of Agriculture reports concluded: "In spite of all difficulties 20,000 farms were established by spring 1920. The lack of inventory is one great obstacle. Many of the agricultural workmen due to this have not succeeded in becoming tenants and therefore oppose the distribution of land. A certain percentage of the new landholders will fall out of the ranks; but the production problem is not considered to be insolvable." An Esthonian critic (A. Busch) in a monograph insisted that live stock and implements were deteriorating and that not a single building had been erected since the law was passed. The transformation of large holdings into small holdings required a new investment of capital, which was totally lacking.

BIBLIOGRAPHY.—Apart from the official publications of the Esthonian Government quoted at length in the non-official periodicals published in Paris and London, sources of information were scanty in 1921. The proceedings of the Paris Peace Conference were not yet accessible. The literature on the subject is either panegyric, propagandistic or detractory. *Mémoire sur l'Esthonie présentés par la Délégation esthonienne à la Conférence de la Paix, 1919;* Martens, *Memoria della Delegazione estone* (Rome, 1919); in German, *Die Esten und die Estnische Frage;* in French, *L'Esthonie et les Esthoniens* (Paris, 1919); *Revue Baltique* (Paris, Sept. 1918, in progress); *Esthonian Review* (London, July 1919–June 1920); *Baltic Review* (London, Aug. 1920, in progress); Oskar Bernmann, *Die Agrarfrage in Estland* (1920); *Courland, Livonia and Esthonia* (handbooks prepared under the direction of the Historical Section of the Foreign Office, 30; London, 1920); Gaston Gaillard, *L'Allemagne et le Baltikum* (1919); Baron Alfons Heyking, *The Baltic Problem* (1919); Russian Liberation Committee, *The Baltic Provinces* (anonym. by Baron Korff, 1919); Alexis Engelhardt, *Die deutschen Ostseeprovinzen Russlands* (3rd ed., 1916). All such publications represent various points of view. (A. M.)

**EUCKEN, RUDOLF CHRISTOPH** (1846– ), German philosopher and religious teacher (*see* 9.878). During the World War Eucken, like many of his academic colleagues, took a strong line in favour of the causes with which his country had associated itself. After the war he became the chief leader of the new idealist movement in Germany, which obtained many adherents among politicians as well as among sections of the general public hitherto averse to the tendencies it represents. The representatives of the main current of this movement regarded Christianity as the culminating point of religious aspirations, but based no hopes upon the Christian churches ever deepening the religious consciousness. Other currents continued to identify themselves more or less with the churches, and a common ground was found in great assemblies of men and women of the younger generation,

generally in the open air, where plans were discussed for strengthening the moral fibre of the nation in view of the overwhelming problems arising out of Germany's political and military collapse.

After 1910 Eucken published the following works and pamphlets: —*Grundlinien einer neuen Lebensanschauung* (2nd ed. 1913); *Können wir noch Christen sein?* (1911); *Erkennen und Leben* (1912); *Die Lebensanschauungen der grossen Denker* (10th ed. 1912); *Die Träger des deutschen Idealismus* (1915); *Mensch und Welt: eine Philosophie des Lebens* (1918; 2nd ed. 1920); *Deutsche Freiheit: ein Weckruf* (1919); *Einführung in die Hauptfragen der Philosophie* (2nd ed. 1920).

**EUGENE, ARCHDUKE** (1863– ), Austro-Hungarian field-marshal, was born May 21 1863 at Gross-Seelowitz in Moravia. In his military career he had become commander of the XIV. (Innsbruck) Corps and army inspector when, before the outbreak of the World War, considerations of health compelled his retirement. It was only after the retreat of the Austro-Hungarian troops from Serbia in Dec. 1914 that the Emperor handed over to him the command of the army holding the Danube–Save line. After the Italian declaration of war the Archduke took over the command on the south-western front. At the time of its greatest extension his constantly changing area of command stretched from the Ortler to the sea. The battles fought under his directions on the Isonzo and on the Tirol front formed a series of successes. As a staff commander the Archduke was associated with Gen. Alfred Krauss (born 1862 at Zara), who was also known as a writer on military subjects. Under the new regulations concerning army commands in Jan. 1918 the Archduke received no further active command. As Grand Master of the Teutonic Order he remained unmarried. His unaffected character made him very popular.

**EUGENICS** (*see* 9.885*), the name coined by the late Sir Francis Galton (from Gk., *εὐγενής*, well-born), and first used by him in his work on *Human Faculty* (1883), for what he defined as the "science of improving stock, which is by no means confined to questions of judicious mating, but which, especially in the case of man, takes cognizance of all influences that tend, in however remote a degree, to giving more suitable races or strains of blood a better chance of prevailing over the less suitable than they otherwise would have had." The word "science" used in this connexion is apt to be a little misleading. "Science" is used to denote two different things; it may mean the knowledge of a particular group of the laws of nature, or it may be used to denote the *art* of applying this knowledge in order to effect a desired object. It is clear from the context that it was in the second sense that Galton intended to use the word "science," and therefore a shorter and perhaps less ambiguous definition of eugenics would be "the application of our knowledge of the laws of heredity to improving the quality of the human race."

The aim of eugenics is therefore not primarily the collection of facts, but the construction and advocacy of practical proposals. The character of these proposals will of course depend on our conception of the laws of heredity, but the study of these laws forms the subject matter of the science of genetics. Genetics is a department of biology; and the last word in all controversies connected with heredity must rest with the biologist.

Like all the other laws of nature, the laws of heredity can only be ascertained by the carrying out of carefully thought-out experiments under standard conditions. It thus follows that these laws must be investigated by dealing with animals and plants since we are not allowed to subject our fellow-beings to experiments or to control their mating. When we deal with human statistics we must therefore interpret them according to the laws which we have deduced, from our standardized experiments on the lower organisms, and in working with these statistics, the help and criticism of skilled mathematicians constitute invaluable aids to research, but mathematics applied to data unsifted by the biologist are valueless.

The popular conception of the best method to improve our race is to improve the environment, and for measures of this kind the American investigators have adopted the term *euthenics*.

"All men are born free and equal," stands in the fore-front of the American constitution; and it is assumed that the differences between them are due to differences in up-bringing, to their mental and material circumstances in fact. If this supposition were justified it followed that the great remedy for many of our social ills was the extension of education, and on this supposition the social reformers of the 19th century have proceeded. Now it may be conceded that in order to bring out the full potentialities of any organism a favourable environment is necessary; if the soil be too dry the seed will either not germinate at all or if it does germinate it will produce but a poor and sickly plant; but all gardeners know that no amount of moisture or manure will ever produce from seed of inferior stock the plants which can be raised from fine varieties. If the poultry-keeper wishes for a large egg supply he must choose the breeds of fowl which he will keep; no matter how he feeds the inferior breeds he will not obtain from them a good yield of eggs.

One of the first questions therefore which presents itself to the eugenist for solution is whether the mental and moral qualities of men are inherited according to the same laws as govern the production of eggs by fowls. Galton endeavoured to find an answer to this question, but the means which he adopted were decidedly crude. For instance, he obtained records of what he termed the good tempers and bad tempers of married people[1] and tried to find out what proportion of the children were good-tempered or bad-tempered; and again he went through old lists of the results of examinations at Cambridge,[2] and tried to show that a large proportion of the sons of those who had attained distinction in these examinations later rose to occupy important positions themselves. These methods certainly did give indications that character and ability were inherited, but they were open to grave objections. Thus it might be said that estimates of good temper and bad temper on the part of observers were unanalyzed haphazard impressions incapable of accurate measurement; and again, so far as the inheritance of mental ability was concerned, it was pointed out that a boy could inherit from his mother as strongly as from his father, and that in the case of Cambridge scholars there were no means of ascertaining the mental capacities of the mothers.

Since Galton's time, however, enormous strides have been made in attacking the problem of accurately measuring mental ability. The extension of compulsory education to all the children of the leading nations of Europe and the standardization of the curricula of education have provided investigators of mental ability with a very large amount of material. After many years' work and thousands of trials on the children of the elementary schools of Paris, Drs. Simon and Binet succeeded in elaborating a series of tests[3] by means of which they could measure the degree of intelligence attained by growing children. The distinctive feature of these tests was their independence of any special type of instruction. They were so framed that, for example, a child on attaining the age of three could be reasonably expected to do the things prescribed for a child of three, and fail to do those allotted to a child of four. For instance:—

At 1 year a child should recognise food.
At 2 years (1) walk; (2) obey a simple direction.
At 3 years (1) point out nose, eye and mouth; (2) repeat two digits; (3) enumerate the objects in an engraving; (4) tell his surname; (5) repeat a sentence with six syllables.
At 4 years (1) tell whether it is a boy or a girl; (2) name a key, knife and a penny; (3) repeat three numerals; (4) point out the longer of two lines.
At 5 years (1) discriminate the heavier of two boxes; (2) copy a square; (3) repeat a phrase with 10 syllables; (4) count four pennies; (5) reconstruct a card cut diagonally into two pieces.

Similar tests were devised suitable to the intelligence of children of every age up to fifteen. At this age the growth of mental capacity as distinct from attainment seems to be complete. If a child of three could perform the tests arranged for a child of four he was said to be advanced; if he could only perform those suitable for a child of two he was said to be backward.

[1] *Natural Inheritance* (1889).
[2] *Hereditary Genius* (1st ed. 1869, 2nd ed. 1892).
[3] For a full account of these tests see "The Measurement of Intelligence," by Dr. T. Simon (trans. by Dr. W. C. Sullivan), *The Eugenics Review*, vol. vi., No. 4, Jan. 1915.

This scale devised for the school children of France has been tested in the elementary schools of Italy and of the United States. It has been found to be right in principle, although tests and ages require some slight adjustment when applied to children of other races than the French.

Now when we apply these tests to the unfortunate people denominated imbeciles and feeble-minded, we make the surprising discovery that some of them, although they may live to an advanced age, are never able to perform the tasks allotted to a child of three and that none of them can do more than pass the tests suitable to a child of ten. Here then is the explanation of mental defect; it is the failure of the mind to develop further than to a certain stage. The next step was to ascertain whether or not this unfortunate character was hereditary, and the merit of solving this, perhaps the most important of eugenic problems, must be accorded to Dr. Goddard,[1] a doctor attached to the staff of the Vineland Institution for insane and mentally defective children in the state of New Jersey. This institution is a charitable one, which takes in defective children and gives them the best education which they are capable of receiving. All the inmates are tested on admission, and at suitable intervals afterwards, by the Simon-Binet scales.

Now Dr. Goddard secured the services of a certain number of educated investigators, who received a special course of training in the institution itself and were then sent forth to investigate the ancestry of the inmates so far as this could be accomplished. This they did by gaining the confidence of the relatives of the inmates, to whom the acceptance of the care of their afflicted children by the Vineland Institution was a great boon, and who were naturally anxious to learn about their progress and quite ready to talk about the first appearance of what to them was an ordinary malady. In this way the investigator was enabled to find out whether any of the brothers or sisters of a particular child were mentally defective, whether his parents or his grandparents had been similarly affected, or whether there were circumstances pointing to some accident as the cause of the trouble. By proceeding along these lines it was possible to draw up an ancestral chart for each inmate of the institution. In this chart a square indicated a male relative, a circle a female; if it appeared that the relative was mentally defective the square or circle was blackened—if on the other hand the relative was clearly normal a square (or circle as the case might be) with the letter N inscribed was placed on the chart. Where definite information was lacking a blank square or circle was added.

The chart was revised at intervals, a fresh investigator being employed for the research on which the revision was based. In practically no case did renewed inquiry lead to the conclusion that relatives formerly regarded as defective were really normal; on the contrary, at every fresh examination more doubtful cases resolved themselves into definitely feeble-minded ones and the child's chart was correspondingly blackened.

The net results of Dr. Goddard's investigations were as follows. In the case of 6,000 children a mentally defective ancestor was ascertained; and about one-fourth of these children were definitely feeble-minded and about one-fourth definitely normal; the mental condition of the remainder could not be ascertained. In the case of 1,500 children there was a definite history of an accident which might be regarded as the cause of the mental condition, and 804 children are classified as of "neuropathic" ancestry, *i.e.* the descendants of epileptic or hysterical parents, a condition which seems akin to feeble-mindedness. It should be remarked that these numbers included not only the inmates of the institution but their brothers and sisters and cousins who were outside and many of whom were quite normal mentally. Where both parents were mentally defective practically all the children were feeble-minded: out of 750 such children investigated only six were reported as normal; and considering the low grade of sexual morality maintained by such people the parentage of these children must be the subject of considerable doubt. In the case of one such family, where both parents were mentally defective, two children out of a large number were normal but these two were *black* and therefore of obvious illegitimate origin. Where one parent was defective and the other, though normal, had a defective ancestor, then as a rule some of the children in the family were defective and others normal. The same results were obtained where both parents themselves were normal but where one of them was descended from a defective ancestor.

Now these results are in accord with the newest and best-attested results of researches into the inheritance of certain characters in the lower animals and in plants; the laws governing this kind of inheritance are termed Mendelian because they were first ascertained by Gregor Mendel, an Augustinian monk in the middle of the 19th century. Mendel's work was unnoticed by most of his contemporaries and was only rediscovered and confirmed by further research in 1900. Briefly the laws which he discovered may be summarized thus:—

(1) In different breeds or strains of the same species characters often appear in pairs so that only one of the pair appears in one strain: such characters are termed allelomorphs. (2) When two such strains are crossed, in the first generation of hybrids only one of the allelomorphs appears: this is termed the dominant character; the allelomorph which fails to appear is termed the recessive character. (3) If the first generation of hybrids be used as parents of a second generation of hybrids, one-fourth of these will exhibit the recessive character, and these if used to propagate a further generation will give rise to nothing but recessives for however many generations propagation may be carried on. (4) In cases (such as plants) where self-fertilization is possible the three-fourths of the second hybrid generation which exhibit the dominant character can be individually tested as to their hereditary potentialities. It is then found that one-third of them (*i. e.* one-fourth of the whole generation) give rise to nothing but dominants, but the remainder (*i.e.* one-half of the whole generation) behave as did the first generation of hybrids, *i.e.* each gives rise to progeny three-fourths of which exhibit the dominant character and one-fourth the recessive character.

These results were interpreted by Mendel as proving that the first generation of hybrids produced two kinds of germ cells in equal numbers, each kind bearing one of the allelomorphic characters, and that these two kinds were mixed at random in fertilization. Bateson and Punnett[2] later gave reasons for believing that the recessive quality of a character was due to the fact that it was caused by the absence of something which was present in the dominant, and that when two germ cells united in fertilization, if one of them bore the dominant character, that was sufficient to ensure the appearance of that character in the resulting organism.

Mental defect is therefore a recessive character due to the want of something in the fertilized egg which gives rise to the mentally defective child, something which is present in the germ from which the healthy child originates. We now understand why two defective parents can give rise only to defective children and why a normal child can spring from the union of a normal and a defective parent, and further why such a child may in turn give rise to defective children as well as to normal ones.

The social implications of this discovery are fundamental and far-reaching. We see at once—and this is in accordance with the experience of the Vineland authorities—why all efforts to raise the mentally defective above a certain level by education are bound to fail. Further, we see that unless such defectives are segregated for life and prevented from breeding they constitute a constant source of potential poison to the race.

If we regard all children who fail to attain a greater mental age than nine as defective, they can be conveniently arranged in three groups, viz. (*a*) those who never attain a mental age of more than three years, who are termed idiots; (*b*) those who never attain a mental age of more than six years, who are termed imbeciles; whilst (*c*) those reaching mental ages of seven, eight and nine years are termed in English law "feeble-minded," but by the American authorities "morons" (Gk. μῶρος, foolish). Neither idiots nor imbeciles constitute a social danger since their incapacity is so great that they are unable to support themselves in the ordinary battle of life and must therefore be maintained

[2] W. Bateson and R. C. Punnett, "A Suggestion as to the Nature of Walnut Comb in Fowls," *Proc. Camb. Phil. Soc.*, vol. xiii, 165. See *Mendel's Principles of Heredity*, by W. Bateson (1909).

in institutions, but morons possess sufficient intelligence to struggle along in the lowest social grade and in the poorest-paid employments, and it is just these grades of society which produce an enormous crowd of children which in former times died out but which our philanthropists now endeavour to keep alive at the expense of taxes levied on the better grades of society.

The gradual lowering of the grade of mental capacity in the whole population which must result from these conditions is not the full extent of the evil. Not only are the morons defective in intelligence, they are also defective in self-control which is the basis of all morality. American investigators have applied the Simon-Binet tests in certain large American cities to the delinquents who appear before police-courts: and their results point to the conclusion that a large proportion of the thieves, prostitutes and habitual drunkards are mental defectives. In one case, to give one example, it was found that 50% of prostitutes were indubitably feeble-minded—and this proportion was arrived at when a large number of doubtful cases had been put down as normal.[1] There seems to be no tendency such as Lombroso postulated in these unfortunates to commit crime for its own sake; their crimes are simply due to an inability to control the tendency to the gratification of their own desires and passions, irrespective of the consequences to others and to themselves.

Dr. Goddard points out that there are two totally different kinds of inebriates to be met with, viz. (1) ordinary people who have lapsed into drinking habits but who are quite capable, if they become sufficiently frightened, of being completely cured, and (2) morons, ready to repent with tears and to sign any pledge, but certain within a week to plunge again into intemperance.

These conclusions which run counter to so many popular prejudices have naturally awakened much criticism and opposition. It should be stated that Dr. Goddard's work has been repeated at various places in the United States, and that similar results have been obtained, but it is to be feared that in many cases his extreme care and the constant repetition of his investigations which he practised have been omitted. Hence Dr. Heron[2] and Prof. Pearson[3] have pointed out that the methods of ascertaining the degree of mental defect were often extremely unsatisfactory and unconvincing and Goddard's methods of ascertaining the feeble-mindedness of the parents and other relatives of feeble-minded children have been criticized as being based on impressions which the investigators derived from mere gossip. On the face of it there is much in this objection, but on the whole Goddard's answer to it is satisfactory. He says first that the investigators were carefully trained so that their judgment could be relied on, and secondly that when different investigators examined the same case, at considerable intervals, they arrived at concordant results. From the point of view of students of heredity it is of far greater importance that the inheritability of mental defect should have been established in the carefully standardized investigations of Dr. Goddard than that obvious blunders should have been demonstrated in many of the parallel investigations carried out elsewhere.

A school of English social reformers of which Dr. Saleeby has been a prominent member have endeavoured to account for most of these cases of mental defect by the action of what they term racial poisons. They maintain that alcohol, when drunk in immoderate amounts, and the toxins of the venereal disease syphilis both attack the germ cells carried in the parents' bodies and not only tend to cause the production of diseased and defective children but that these children if they survive and reproduce likewise give rise to imperfect offspring. Now it is conceded on all hands that the toxins of syphilis do in certain cases penetrate the placenta, and interfere with the growth of the embryo; nay more, that the embryo itself may become infected. As a result horribly malformed and diseased infants are born, but when these survive they appear to get rid of the syphilitic infection before the completion of adolescence, and there is no reliable evidence that their germ cells are defective or diseased.

With regard to alcohol it seems clear that immoderate indulgence in alcohol about the time of conception and during pregnancy tends to produce children with weakened constitutions, but again there is little or no evidence that their germ cells are weakened. It is true that one investigator (Stockard) [4] claims to have proved that by making guinea-pigs inhale the vapour of absolute alcohol for several hours daily he succeeded in causing them to produce weakened offspring. In these young guinea-pigs injuries to the eyes and nervous system were prominent, and these weaknesses were transmitted in increased degree to subsequent generations without further exposure to the influence of alcohol. The stock died out in the fourth or fifth generation. It would, however, be exceedingly rash to generalize from these experiments. Pearl[6] repeated them, using the domestic fowl instead of the guinea-pig, and found that the chicks produced by alcoholized parents were on the whole hardier than those whose parents were left untouched. The present writer has repeatedly introduced large quantities of absolute alcohol by subcutaneous injection into the bodies of white mice, so that they passed into a state of complete insensibility, yet even after repeated treatment of this kind they recovered and became the parents of offspring which were apparently quite healthy. Finally, considering the enormous extent to which alcohol has been consumed by the British nation during the last 300 years it is obvious that if any permanent injury had been done to the germ cells, it should be now a diseased and crippled nation instead of a virile people such as it sufficiently proved itself to be in the World War of 1914–8. That the causes of mental defect cannot be found in the alcoholism of the parents was definitely proved by Goddard. Of 300 children born of defective parents not alcoholic 99% were mentally defective; and of 130 children born of alcoholic defectives 98½% were defective.

Mental defect must be assigned to the same cause as that which produces other types of Mendelian recessive. It is the common experience of all who have bred large numbers of animals or cultivated large numbers of plants, that from time to time Mendelian recessives turn up, and no more definite cause for their appearance has ever been suggested than that of "accidents of division" in the ripening germ cells. These recessives in many cases show varying degrees of defect which closely recall the grades of mental defect met with amongst the feeble-minded. For instance, in the cultures of the fruit-fly *Drosophila ampelophila* made by Prof. Morgan and his pupils various grades of blindness have appeared. The normal pigment necessary to the function of vision is of a dark red colour: complete albinos in which the eyes are white frequently occur, and also various imperfect grades of red classified by Morgan as cherry, eosin, etc. The occurrence of these defectives in the fruit-fly is certainly not attributable either to syphilis or to alcohol, and there is no more reason to attribute the occurrence of mental defectives in the human race to these causes than there is to assign these "race-poisons" as causes of the defectives in the fruit-fly.

As the results of the inquiry into the nature of human heredity are so startling and seem to involve such grave consequences it is obviously the first step in eugenic endeavour to make them as widely known as possible, so as to prepare public opinion for the practical steps which sooner or later must be taken. With this object the Eugenics Record Office was established in America by the Carnegie trustees and placed under the able presidency of Dr. Davenport. In England Sir Francis Galton by a bequest in his will founded a chair of Eugenic Research in University

College, London, to which his friend Prof. Karl Pearson was appointed. Prof. Pearson has established a biometrical laboratory in which a large amount of valuable statistical work has been accomplished and much evidence adduced bearing on such questions as the inheritability of consumption, etc. The Eugenics Education Society, the object of which was not research but an endeavour to make the results of research widely known, was founded in London under the honorary presidency of Sir Francis Galton. Its first president was Sir James Crichton-Browne, its second president Mr. Montagu Crackanthorpe, to whom succeeded Maj. Leonard Darwin in 1911.

The cause of eugenics owes a great debt to Maj. Darwin for having pointed out clearly wherein fitness to survive in the eugenic sense really consists. On this subject much confusion has reigned not only in the minds of the general public but also in the minds of the first enthusiasts for eugenic reform. Attention was at first concentrated on physical health and muscular development, and it was an easy task for opponents to point out that the "big blonde beast" of Nietzsche was not the most desirable type of man, and that men of great talent and initiative often were so in spite of the handicaps of physical disease or infirmity, that Caesar and Mahomet both suffered from epilepsy and that Robert Louis Stevenson died of consumption.

As Bateson[1] has well put it: "We animals live not only on account of but in spite of what we are." Maj. Darwin[2] has emphasized the fact that the decisive factor in the human struggle for existence is general ability and that, broadly speaking, when we compare together members of the same profession—the greater the ability the greater the pay.

It is an easy task for the critic to point to individuals who though able and virtuous have become poor, and to others who though rich are idle and vicious, but these exceptional cases do not detract from the generalization insisted on by Maj. Leonard Darwin that on the whole the poor deserve to be poor and that their ranks are continually swollen by the descent of the unfit from the superior strata of society. It may be added that if the rich persist in being idle and vicious then riches have a strong tendency to disappear—a fact borne witness to by the Lancashire proverb, "It takes three generations to pass from clogs to clogs"; further, that if the able and virtuous poor persist in well-doing they invariably rise to affluence in one or two generations, so that these apparent exceptions to Maj. Darwin's generalization have a way of righting themselves.

### Birth Control

The Dean of St. Paul's (the Rev. Dr. Inge),[3] a prominent member of the Eugenics Education Society, has pointed out that during the first half of the 19th century, when no free education was provided, there were far more emergences of men of talent and ability from the masses than during the second half when every effort had been made to "raise the poor" by education, sanitation and doles. Maj. Darwin has called attention to the discovery of harmless and painless means of sterilization by X-rays: so that limitation of the birth-rate by preventing conception is now easily accomplished.

Formerly the natural fecundity of all classes of society was allowed to flow on unchecked: even under these circumstances larger families were born to the poor than to the rich because the poor marry early and improvidently, which is one of the main causes of their poverty, but the greater death-rate amongst their children prevented the poorer strata of society from increasing relatively to the rich. Now, however, the rich limit their families to a number which they can easily support, and this number tends to become smaller and smaller as heavier taxation is levied to provide for the survival and education of large families of the poor. Eugenists contend that the State is in this way deliberately cutting off its best stocks which raised it to greatness in the past, and on the continuance of which its whole future depends. Against this whole policy the Eugenics Education Society has raised a continuous protest and the Eugenics Record Office of America has published a valuable series of bulletins[4] showing the awful progeny of criminals, paupers and lunatics that have sprung from a single worthless family during the last 100 years, and some American states have passed somewhat hastily conceived laws designed to cause criminals and idiots confined in state prisons to be sterilized.[5]

It is indeed obvious that mere restraint of marriage will avail little since it by no means prevents illegitimate union, and amongst the lowest strata of society the marriage ceremony is frequently dispensed with. The only way in which the cruel methods of natural selection can ultimately be avoided is by the sterilization of the unfit; in a word, by preventing parents who are unable properly to support the offspring which they have already produced from producing any more. A first feeble step in this direction may be found in the regulation which until recently was enforced in English poorhouses, forbidding husbands and wives to live together, but public opinion would now be opposed to any extension of this principle: people generally are so obsessed with the liberty of the subject that the liberty of the depraved and worthless to pollute society by a stream of worthless progeny has not been seriously challenged.

The reckless reproduction of the poor in England is sometimes defended on the ground that it contributes to the population of the British overseas dominions and so to the up-building of the British Empire. But on closer analysis we find that this defence will not hold. The great British dominions have very clear conceptions about the type of immigrant whom they desire and whom alone they will admit. They desire people of initiative and adaptability and these are just the qualities which are lacking in our submerged tenth. Incidentally the submerged tenth are without the means of emigration, and the dominions have wisely refused to accept immigrants who come to them on "assisted passages." As things were in 1921 England was being threatened more and more with the fate of becoming a reservoir of the unfit, since it is the fit who both emigrate and limit their families in accordance with their means. The Dean of St. Paul's has pointed out that between the years 1700 and 1800 the population of Great Britain increased by 30% but that between 1800 and 1900 it increased by no less than 300%. Statistically, therefore, it appears that the British Isles are rapidly approaching a condition of over-population, even if they have not already attained it. What is needed is not an increase in the birth-rate but a rigorous selection of those who are to be the parents of the future generation. In former ages this selection was accomplished by famine and pestilence. Ireland in 1846 had eight millions of starving peasantry living a life little better than that of the pigs which they housed in their cabins. The famine and emigration in 40 years reduced the population to four millions who might be described as thriving farmers. The Black Death in the 14th century wiped out two-thirds of the population of England; the following century was the most prosperous and happy time for the agricultural labourers of England of which there is any record. Well has it been said: "In the good old days people died in the country as fast as they now die in the slums of cities, and they died in the cities as fast as white people die on the coast of Guinea." If things go on as they are such a selection will again sooner or later be accomplished by nature; the whole purpose of eugenic propaganda is to make clear that we are approaching such a catastrophe; and to endeavour by humane and wise methods to avert it; to so arrange matters by legislation that the enterprising and provident shall be the parents of the future race and that drunkards, wastrels and reckless shall be debarred from handing on their vices to posterity.

**EUGÉNIE** [MARIE-EUGÉNIE-IGNACE-AUGUSTINE DE MONTIJO] (1826–1920), ex-Empress of the French (*see* 9.885). During the World War she turned her home at Farnborough into a military hospital. She followed with intense sympathy the fluctuating fortunes of France, and lived to see the injustice of 1871 corrected by the Treaty of Versailles. She died on July 11 1920 at Madrid, while on a visit to her nephew, the Duke of Alva. A few days previously she had undergone an operation for cataract, and succumbed to an attack of uraemia.

**EUROPE** (*see* 9.922).—In dealing with the general European situation during the years which intervened between 1909 and the outbreak of the World War, the historian is faced with the fact that the importance of this period lies in the conclusion. Always there is before us the problem: was the war with which it terminated the inevitable outcome of deep-seated causes, or was it an avoidable result of demonstrable blunders and crimes? A consideration of this problem makes it necessary to revert briefly to previous events. Much which in 1910 was obscure has been elucidated by later publications; much which was then a conjecture or hypothesis has been verified; and much which could then only be tentatively suggested can now be frankly said.

*The Triple Alliance.*—The chief characteristic of the first years of the 20th century is the rivalry of the two political groups into which Europe was divided. As we can now see, the establishment of the Triple Entente (England, France, Russia) was a necessary and inevitable counterweight to the Triple Alliance (Germany, Austria and Italy); for this latter alliance, so long as it stood alone, gave to Germany a preponderance upon the continent of Europe so great as to be a permanent check on the free diplomatic activities of other states, and possibly a danger to their independence. It is true that the original alliance between Germany and Austria in 1879 had been a method of maintaining peace and securing the *status quo*. At that time Germany under Bismarck was, as he said, a satiated state; all that it required was time and peace for the development of its internal resources. In order to secure this he had built up an extraordinarily complicated system of alliances and agreements. We have first the original Austro-German Alliance of 1879, which was repeatedly renewed and remained in force until the outbreak of the World War. This treaty, which was published in 1888 in an incomplete form, bound the two empires to help each other in case it was attacked by Russia; if either was attacked by a third Power, the other was to observe at least a benevolent neutrality, and if the attacking Power was supported by Russia, then to come to the assistance of its ally. Side by side with this treaty of mutual defence against Russia, in 1881 Germany and Austria entered into an alliance with Russia, the chief point of which was a mutual engagement to act together in all Balkan matters. This treaty was renewed in 1884 for three years. It lapsed in 1887, and for it was substituted the "Reinsurance Treaty" between Germany and Russia alone, by which each party agreed to maintain benevolent neutrality towards the other in case of a war with a third Power. This was not to apply in the case of a war against Austria or France if this resulted from an attack against one of these latter Powers by one of the parties to the treaty. In addition, Germany recognized the rights historically acquired by Russia in the Balkan Peninsula, and particularly the legitimacy of her preponderant and decisive influence in Bulgaria and in Eastern Rumelia. There was to be no modification of the territorial *status quo* in the Balkans without previous agreement and the principle of the closing of the Straits was reaffirmed. This lapsed in 1891; Caprivi is reported to have said that it was too complicated for him. Meanwhile, in 1882, the Triple Alliance was arranged between Austria, Germany and Italy, the essential point of which was that Germany and Austria were bound to come to the assistance of Italy if she was attacked by France, and similarly, Italy to come to the assistance of her allies if either of them was attacked or engaged in a war with two or more Great Powers; a special protocol stated that this treaty could not in any case be regarded as being directed against England. In 1883 Rumania, by a separate treaty with Austria, to which afterwards Germany and Italy adhered, became attached to the group, the allies binding themselves to defend Rumania if she was attacked. The text of this treaty was kept strictly secret; it was a personal act of the King of Rumania, and was communicated to no one except the prime minister. In 1887 the Triple Alliance was renewed and extended, the two German Powers now undertaking to support Italian interests in North Africa, both in Tripoli and Morocco; these clauses included an undertaking to support Italy in any action that she might take to safeguard her position, even to war with France. In 1891 the third treaty of the Triple Alliance reasserted in a strengthened form the Mediterranean obligations to Italy; a very important clause (VII.) determined that every advantage, territorial or other, obtained either by Austria or by Italy in the Balkans should be based on the principle of reciprocal compensations.

These four Powers formed a coherent group, but to it other states were more loosely attached. In 1887, when there were cordial relations between the British and the German Governments, Lord Salisbury, by an exchange of notes, came to an agreement with Italy and Austria to maintain the *status quo* in all the eastern waters of the Mediterranean, while Italy undertook to support Great Britain in Egypt; Great Britain on her side expressing her intention to support the action of Italy in North Africa. There was also an agreement between Italy and Spain as to Morocco, and at this time Serbia also was attached by a separate treaty to Austria.

We see that this very elaborate structure of treaties and agreements was really approximating to a general European system into which in one form or another there were brought Austria, Italy, Rumania, Spain, Serbia, Great Britain, and even Russia; the whole object was the isolation of France, and it served its purpose of securing to Germany full and peaceful enjoyment of all that she had gained by the war of 1870–1. The extension of this system to the Mediterranean was advantageous to Great Britain in so far as it tended to strengthen her position in Egypt. The pivot was Germany and the centre of gravity was the German army; this it was which held the whole together. It was a system in which Europe could acquiesce only so long as the policy of Germany was passive; a reaction must inevitably arise if Germany began a policy of active expansion. With the accession of a new emperor and the resignation of Bismarck, the Triple Alliance, while unchanged in form, acquired a new meaning. The period of rest and recuperation in Germany was over, and the new empire, conscious of its strength, began to stretch out with great ambitions towards the other quarters of the globe. The immense growth of German wealth, the skill with which the mineral and agricultural resources were developed, and the expansion of manufactures naturally led to an extension of foreign trade. German agents, supported by German bankers, were to be found in every part of the world; there was a great development of maritime shipping, and this naturally led to the acquisition of extra-European dependencies and the extension of political interests. The first years of the new Emperor's reign appear a tentative experiment; with the appointment of Herr (afterwards Count and then Prince) von Bülow, first as Foreign Secretary and afterwards as Chancellor, the new tendencies became the deliberate and conscious policy of the German Government. It was inevitable, even with the best possible intentions, that numerous causes of friction should arise with other nations, and especially with Great Britain, for there was no part of the world (except perhaps South America) in which the expansion of German influence did not touch British interests.

*Franco-Russian Alliance.*—Germany could embark with full confidence on this great policy of expansion just because her

essential security at home was so well guarded; hers was the only alliance on the continent. But ever since 1870 acute observers had foreseen that, some day or another, France and Russia would join together in order to redress the balance of the continent. This event took place in Aug. 1891. The agreement (which was formulated in an exchange of notes) was based on "the renewal of the Triple Alliance and the more or less probable adhesion of Great Britain to the political views of this alliance." It contained two clauses: one that the two Governments would agree together on any question of such a kind as to endanger the general peace; and the other that, in case either party was menaced by an attack, they would agree together on the measures to be taken. Two years later, however, after long negotiations in which many difficulties were encountered, this was supplemented by a military convention (Dec. 1893–Jan. 1894): if either France or Russia were attacked by Germany, France or Russia respectively would apply all her forces to attack Germany. If the forces of the Triple Alliance, or one of the Powers of which it consisted, were mobilized, France and Russia would immediately mobilize. The number of troops to be employed was specified, and it was agreed that there should be joint action between the general staffs and interchange of all information relative to the armies of the Triple Alliance.

But even after this there was little real cordiality in the relations between Russia and France. Russia, moreover, was occupied with Asiatic affairs, and had come to a friendly agreement with Austria as to the Balkans which was confirmed by an exchange of notes on May 8 1898. The internal dissensions of France (it was the time of the Dreyfus trial) weakened the influence of that country abroad. France indeed was protected against the danger of a new attack from Germany, but received little support from Russia in the normal discussion of diplomatic matters. The essential change took place at the turn of the century. Up to this period Great Britain had held aloof from the continental system. The British occupation of Egypt had resulted in a continued estrangement from France, and on the whole there was a tendency towards a close understanding with Germany and the other members of the Triple Alliance. This understanding was now broken. The first serious differences arose out of South African affairs. The Krüger telegram of 1896 was a flash of lightning; no storm followed, but this and the intense animosity against Great Britain shown during the Boer War were symptoms that could not be neglected. By a large party in Germany the consolidation of British power in South Africa was regarded as the loss of a sphere which they had marked out for German expansion. Though the matter is still extremely obscure, there is no doubt that during 1898, 1899, and 1900 proposals were discussed in every chancellery in Europe for a European coalition against England, and the impression produced in other countries was that such a coalition would be welcomed by Germany. Equally important was the altered attitude of Germany towards the Near East. The great and legitimate expansion of German commercial and economic interests was accompanied by a growing cordiality with the Porte, and during his visit to Damascus in 1897 the German Emperor proclaimed himself the protector of all Mahommedans throughout the world—an utterance which from anyone but him would have been justly regarded by France and Great Britain as an unparalleled provocation. There was also a serious conflict of interests in the Far East. The evidence which came from many sources was sufficient to make it obvious to every British statesman that a continued political isolation was dangerous. England must have friends, and friends on whom she could rely.

From 1898 to 1901 advances were repeatedly made to Germany by Great Britain, and the project of a definite diplomatic understanding, nay even of a defensive alliance, was ventilated. The suggestions were accompanied by warnings that if an arrangement with Germany was not reached, then recourse would be had to the opposed alliance. The offers were rejected; the warnings disregarded. To the German Foreign Office, to Prince Bülow and to the Emperor, it was an axiom that there could be no real friendship, as they said, "between the whale and the bear." They feared, or professed to fear, that an alliance with England would only mean that they would be used as a military advance post against Russia; in the case of war the brunt of the fighting would fall upon them, while Great Britain would gather up the spoils in Asia. "The danger was imminent that if Germany allied herself with England she would have to undertake the rôle against Russia that Japan assumed later single-handed." They believed that they could do better business by playing off the rival empires against one another, by refusing to commit themselves either to Russia or to England, and by using the rivalry to extend their own influence and possessions.

*The German Navy.*—But there was another influence at work. One of the chief tasks which the German Government had set itself was the building of a great war fleet. It was the considered opinion of German statesmen that, if they were to come to a friendly diplomatic arrangement with England, this would inevitably compel them to limit their naval development; they affected to think that a fleet built by a Germany friendly to England would be a fleet built under patronage and limited by the British insistence on superiority at sea. This they did not desire; they preferred, therefore, full freedom to build against England, trusting that it might be possible to avoid a serious conflict during what Prince Bülow calls the "danger period of construction." It was indeed the new naval ambitions, more even than the rejection of the British offer of an alliance, that conditioned the whole European situation. After all, in 1887 Bismarck had offered an alliance to Lord Salisbury, and the rejection of this offer did not mean any serious misunderstanding. The building of the German fleet was an action of a very different character. It could only be compared to the similar work by which from 1857 onwards the Prussian army, after a period of comparative stagnation and inefficiency, was brought up to the highest point of perfection, and we know how this great instrument of war, when perfected, was used to further Prussian policy. There could be no doubt that the navy, when completed, would also be used for the same object, and in fact the responsible spokesmen of Germany took care to leave no doubt on this point. They wanted the fleet to support their diplomacy. In the memorandum which accompanied the great Navy bill of 1900 this was clearly stated. The navy must be such that, "even for the greatest sea Power, a war with it would involve such risks as to jeopardize its own supremacy."

It would be an error to suppose that the German Government were deliberately looking forward to forcing a war with England. Still more misleading to assume, as so many did in England, that the object was an invasion. There has never been forthcoming any evidence of any kind to justify the belief that the German military and naval programme included the landing of a hostile force upon England's shores. The danger was of quite a different character, but it was none the less serious. The calculation was that if there was a fundamental difference between British and German policy, the possession of a great fleet would enable Germany to get her way, because England might be put in such a position that she would not dare to risk war. And what was the kind of point on which such a difference of policy might arise? Had the German fleet been in existence during the Boer War, there can be no shadow of a doubt that it would have been used to support European intervention. And again, it had become the avowed policy of the German Emperor to use his friendship with the Sultan as a means of winning the confidence of the Mahommedan world, and this—we have his own words for it—was an instrument which might in necessity be used to render impossible the position of England in Egypt or to arouse difficulties in Mesopotamia, in Persia, in India itself. It was the calculation that if any such controversy arose, Germany would not be alone; if she were allied to some other Great Power which possessed a formidable navy—Russia, France, Japan, or the United States—the predominance at sea, on which the very existence of the British Empire depended, would be imperilled.

It is not necessary to enter into details of the German fleet, nor to discuss the very complicated controversies which constantly recurred. It is sufficient to point out the main out-

standing facts which are beyond dispute. The building of the German fleet was governed by the Law of 1900 (that of 1898 was purely preliminary), which was amended in 1906, 1908 and 1912. The original Law determined that the permanent establishment of the fleet should be 38 battleships and 20 armoured cruisers; each ship was to be replaced once every 25 years. By this the standard of building was finally set down. The Act of 1908 determined that battleships and cruisers were to be replaced once every 20 years instead of 25. That of 1912 increased the number of battleships and cruisers to 61. The effect of this would be that, when the programme was completed, Germany would have five squadrons of battleships, of which three were to form the active fleet, two the reserve. In order to understand the full effect it must be remembered that the Law, though it determined the number of vessels, did not deal with their character, size, or fighting power. When dreadnoughts and super-dreadnoughts were introduced, an old ship of (say) 10,000 tons would be replaced by one of 25,000 to 27,000 tons with a corresponding increase in speed and armament. Moreover, especially by the last Law of 1912, arrangements were made for a very great addition of smaller vessels, destroyers and submarines, and above all for keeping the personnel of the navy at such a standard that the whole of the fleet would be available at any time of the year. The total effect was that there was stationed in the Baltic and in the North Sea a fleet stronger than any other except that of Great Britain, and larger and more powerful than the whole of the British fleet had been 20 years before.

This menace was one which had to be met. No child could suppose that it would not affect the whole trend of British policy. The Germans themselves knew this well. What they feared was that England would attack while she still enjoyed her previous naval supremacy and before the German fleet had grown large enough to be dangerous. But this policy of a "preventive" war was never even seriously considered by responsible British statesmen. Their answer was the only possible one. In the first place the British fleet must be strengthened and its whole organization altered. A fleet, like an army, must be found in the place where it is wanted. In the old days the North Sea had been empty of ships; it was in the Channel, in the Mediterranean, in the Atlantic, that the British fleet was placed. The centre of gravity was the Straits of Gibraltar. Circumstances were now changed, and so a great reorganization was effected by which outlying stations were denuded of ships and the bulk of the fleet was stationed in the North Sea.

The Mediterranean had also, however, to be guarded. Austria was increasing her fleet, and Italy was an ally of Germany. As early as 1900 a naval agreement (this has not been published) had been made between the three Powers of the Triple Alliance. To meet this danger in 1912 it was agreed by England that France should concentrate the greater portion of her fleet in the Mediterranean; in the event of a common war with Germany it would fall to the British fleet to defend the northern and western coasts of France. In the same year a naval convention was concluded between France and Russia; with the building of the Kiel Canal the importance of the Baltic in naval strategy had increased. In 1913 a further naval convention between the three Powers of the Triple Alliance was made, and in May 1914 proposals were made for naval conversations between Russia and Great Britain; it is to be noted that at the end of June in the same year the enlargement of the Kiel Canal, by which the biggest ships could pass through it, was completed.

All this was not enough. The German plan was based on the assumption that Germany would be able to gain further allies in addition to those she already had. England also must have allies. Now that Germany was becoming the second naval Power, England could no longer afford to regard with equanimity German military predominance upon the continent of Europe, for this might eventually mean the further weakening of France and, whether by war or by diplomacy, German control over the Low Countries. It might also mean the pressing down of German influence through the Balkans into the Mediterranean. It must never be forgotten that the acts of the Triple Alliance dealt not only with the continent of Europe, but with the Mediterranean and the shores of Africa. The success of the German schemes required one of two things, either an alliance with other states against England, or such increase of German preponderance that they would become, for political purposes, subject to German will. It was necessary, therefore, for England to guard against either contingency, and she could only do so by entering into a firm understanding to join with them in resistance to any unprovoked act of German aggression.

These considerations were so weighty that alone they are sufficient to explain and justify the action of the British Government. The further information which has now become available completely substantiates them. We now know from the letters of the Kaiser to the Tsar, which were published after the Russian Revolution, that throughout the whole of the reign of Nicholas II. the German Emperor had been using the strongest personal pressure upon him to bring about an alliance between Germany and Russia, the point of which was avowedly directed against Great Britain, an alliance into which France would be forced to come. This had been his policy long before the establishment of the Entente with France; whatever the subject of the diplomatic negotiations at the moment might be—whether it was Armenia or Crete or South Africa or Egypt, neutrality during the Russo-Japanese War, or Morocco—always we see the same ambition. He hoped to create trouble for India by encouraging a Russian move on Afghanistan, and for this purpose to arouse the slumbering passions of Islam: "Remember what you and I agreed upon at Peterhof, never to forget that Mahommedans were a tremendous card in our game in case you or I were suddenly confronted by a war with the certain meddlesome Power." He encouraged Russia to give support to Turkey as against Great Britain in the Persian Gulf:—

> "Last but not least, an excellent expedient to kill British insolence and overbearing would be to make some military demonstrations on the Perso-Afghan frontier. . . . Even should the forces at your disposal not suffice for a real attack on India itself, they would do for Persia."

All this culminated when on July 24 1905 he persuaded the Tsar to sign the Treaty of Björko, a secret alliance against England which it was his hope would afterwards be joined by France. This is the kind of method by which he professed to be guarding the peace of Europe. The judgment of King Edward made to a Danish diplomatist may be recalled: "I will admit this, that with a man of so impulsive a temperament as the German Emperor at the head of the greatest Power in Europe, anything may happen." This correspondence was secret, but in diplomacy there is no absolute secrecy, and the rumours of it must be taken into account if we are to understand the profound distrust which was felt for Germany during these years.

*Franco-British Entente.*—These were the circumstances in which a great change of policy took place. The first step was the British alliance with Japan. In this it had originally been contemplated that Germany should be a partner. But Germany did not accept the opportunity offered her, and, in addition, German action over the Manchurian agreement showed that no confidence could be placed in any German engagement. The alliance therefore was one between Japan and Great Britain alone. In 1904 a colonial agreement was reached between England and France, by which the numerous points of friction between the two countries were settled. The essence was that France recognised the British position in Egypt. To do so was a bitter blow to most cherished French traditions and ambitions. In return for this Great Britain recognized the special position of France in Morocco and gave up to France her claims and interests. This agreement in its original inception had, at any rate in England, no special point directed against Germany. It was probably due chiefly to Lord Cromer, but his efforts were supported by Lord Lansdowne and King Edward VII. The object was merely to clear away the outstanding causes of controversy with France, but it was to have far-reaching results.

This agreement was quite unexpected and very unwelcome in Berlin. The whole basis of German diplomacy was cut away.

Europe at once took on a new aspect. In the ordinary diplomatic negotiations Germany must look forward to a situation in which she was confronted no longer by disunited and antagonistic States, but by great Powers, acting in union and coöperation. Even the Triple Alliance itself was shaken, for it was obvious that Italy could not be depended upon in any serious conflict with both France and England. It must therefore be the chief object of German diplomacy to drive a wedge between England and France. For this reason, from this time onwards, every diplomatic incident, even of minor importance, at once reverberated throughout the whole of Europe. This is illustrated by the Morocco affair. Morocco was of great importance to France; it was essential to England that no hostile Power should be established on the north-western coast of Africa; apart from this, Morocco was merely of trivial importance to the rest of the world, including Germany. But Morocco was made the test of the Entente. Germany, taking advantage of the temporary crippling of Russia by her military and naval defeat in the Far East and the internal disturbances which followed, brought the full weight of her military superiority to bear upon France, and thereby forced her into a conference and brought about the resignation of Delcassé. This action defeated its own object. It cemented the union between France and Great Britain, and as soon as it became obvious that France, by entering into this union, exposed herself to the threat of war, it was inevitable that England should take steps, if necessary, to protect her new friend. It was the threats by Germany which gave a military side to what had at first been merely a diplomatic arrangement.

No doubt the French handling of the whole matter was open to criticism, but there was a peculiarity about the arrangement of 1904 which placed Great Britain in a delicate position. As was pointed out at the time in France, England, while she gained definite and defined rights which France surrendered to her in Egypt, gave in exchange only eventual rights in Morocco; France, in return for a definite surrender, got nothing but hopes; England acquired Egypt, France merely the prospect of acquiring Morocco. In these circumstances there was obviously an absolute obligation on Great Britain to see to it that her support of France in Morocco should not be half-hearted; had this support been withdrawn simply because some of the subsequent details of French action were open to criticism, then the worst possible construction might have been placed on the good faith of the British Government; it would have appeared that, after having secured themselves in Egypt, they had seized on a subterfuge so as to avoid carrying out their side of the agreement.

*Anglo-Russian Entente.*—Not only did the German attempt to separate Russia from France fail, but in 1907 an arrangement was made by which the outstanding points of difference between Great Britain and Russia in Tibet, Afghanistan and Persia were settled. The approximation between the two empires, which had for so long been in a state of complete rivalry, was cemented by a meeting between King Edward VII. and the Tsar, which took place at Revel in June 1908. The chief and almost only subject of discussion was the state of affairs in the Balkans, and it was agreed that there should be common action for bringing about a reform in Macedonia. Very misleading statements with regard to these conversations have been constantly repeated by high authorities in Germany, as, for instance, that the definite understanding was arrived at that the two Powers should attack Germany together in the year 1916. There is no truth of any kind in this. The meeting was followed shortly (Aug. 12) by one between King Edward and the Austrian Emperor at Ischl. This also has been the subject of equally erroneous statements, as, for instance, that King Edward tried to persuade the Emperor to secede from the alliance with Germany. This is quite untrue, and was not in accordance with the principles of British policy. The subjects of discussion were very different. The Austrian Emperor gave an undertaking that his Government would not take any isolated action in the Balkans without informing and consulting the other Powers, and the King tried to induce him to use his influence to dissuade Germany from continuing the increase of the German fleet. The whole object was the maintenance of peace, and much would have been done to secure this if a stoppage could be put to the rivalry in shipbuilding between England and Germany, and if no surprise action was taken in the Balkans.

*The Annexation Crisis, 1908.*—It was the contrast between the language used by the Emperor Francis Joseph on this occasion and the action of Austria in the sudden annexation of Bosnia and Herzegovina eight weeks later which explains the intensity of feeling shown by the British Government and Sir Edward Grey as to the latter point. Apart from this and the general principle of the sanctity of treaties, they foresaw how dangerous would be the effect of the joint Bulgarian and Austro-Hungarian action upon public opinion in Turkey. It was the annexation which more than anything else brought to a head the passionate national feeling among Christians and Moslems to which all the wars which followed were due, and the conclusion of the crisis was reached in such a way as to leave the most intense animosity in Serbia against Austria, and to insure that the full support of Russia would be given to Serbia and that henceforward the Balkans would once more become the field for the activities of Russian diplomacy, which had never been scrupulous in the methods which it used.

The episode is important, for in it is to be found the explanation of much which happened in 1914. Just when it seemed as though the very prolonged and acrimonious controversy might be reaching a conclusion, Count Pourtalès, the German ambassador, delivered to M. Isvolsky "a peremptory demand" that Russia should without conditions agree to the abrogation of Article 25 of the Treaty of Berlin, that is, should recognize the annexation. It would no doubt be wrong to speak of this as an ultimatum; there was no threat of war; it may be described rather as a diplomatic ultimatum; an immediate decision was asked for, and it was intimated that, if the answer was unfavourable, Germany would "*lâcher l'Autriche sur la Serbie.*" It is important to understand what this threat—for it was a threat—implied. A war between Austria and Serbia would have placed Russia in a most disadvantageous position; weakened as she was, she could not have come to the help of Serbia, because under the system of alliances Germany would, if necessary, come to the help of Austria. It was in fact a threat that, if the demand was not complied with, Austria, depending upon the ultimate support of the German army, should be given *carte blanche* to free herself of Serbian opposition. It may be added that Germany showed some disposition to use a similar threat to England. Before this, Russian resistance collapsed; they agreed to the German demand without even consulting France and Great Britain. The success was a notable one, but it was dangerous. It was one which could not be repeated. Russia had given way to threats once; she could not afford to do so a second time. It left an intense feeling of indignation in St. Petersburg, which persisted, and became one of the most dangerous factors in the European situation. Personally M. Isvolsky, who soon resigned the post of Foreign Minister, henceforward became the active partisan of an anti-Austrian policy, and was only anxious to revenge himself for the humiliation which had been placed upon him first by Count Aehrenthal and secondly by Germany. The German Government, it is true, did their best to smooth away the impression caused by the harshness of their action, and, after having shown Russia how little the Entente was able to defend her against the Triple Alliance, attempted to win Russian friendship. But the effect of these efforts was obliterated by the German Emperor, who, in a visit to Vienna in the autumn of 1910, took occasion to recall how he had come to the help of his ally "in shining armour."

*Agadir.*—The annexation crisis had occurred at a moment when the relations between France and Germany were comparatively friendly; an attempt had been made at establishing economic and financial coöperation in Morocco. An awkward episode (the German consul at Casablanca was inducing soldiers of the Foreign Legion to desert and was arrested) was settled by arbitration. But this coöperation did not last long. The ambitions of the Colonial party in Germany could not be reconciled with the complete political control which France aimed at. A

new and very serious crisis arose in 1911. The French, in consequence of a civil war in Morocco, followed by the abdication of the Sultan, advanced to Fez. This appeared to show a desire to disregard obligations of the Convention of Algeciras. Germany, in order to support her claim to be consulted, took a step which, as so often happened, could be interpreted as a threat. She sent a small ship-of-war to Agadir. It was of course assumed, not only abroad but in Germany itself, that this action meant that the German Government proposed to claim part of the western coast of Morocco and were even intending to land troops in order to enforce this claim. It seems probable that the German Government themselves had not at the moment really made up their minds precisely what they wanted. The obvious answer to this German move would have been the dispatch of a French or British warship—a policy which was strongly pressed by some of the French. The combined wisdom and moderation of the British and French Governments prevented them answering a threat by a threat, but the renewal of the old methods, the clear intention of once more forcing France into separate conversations without England and thereby extorting unwelcome concessions, could not be overlooked. A final understanding between France and Germany would have been welcomed by the British Government, but they could not stand aside and see France forced under the threat of war to cede to Germany either a position in Morocco itself or quite excessive cessions elsewhere. In a speech at the Mansion House on July 21, Mr. Lloyd George, then Chancellor of the Exchequer, said:—

"I conceive that nothing would justify a disturbance of international good-will except questions of the gravest national moment. But if a situation were to be forced upon us in which peace could only be preserved by the surrender of the great and beneficent position Britain has won by centuries of heroism and achievement—by allowing Britain to be treated, where her interests are vitally affected, as if she were of no account in the cabinet of nations—then I say emphatically that peace at that price would be a humiliation intolerable for a great country like ours to endure."

Shortly afterwards separate conversations were begun between Germany and France on the basis that Germany would agree to disinterest herself in Morocco completely, receiving in return territorial concessions in other parts of Africa. There were many anxious moments, for some of the German demands were excessive, but eventually an agreement was reached by which France surrendered to Germany important parts of her possessions on the Congo. As in the previous Morocco discussions, the importance of the episode lay not so much in the immediate question at issue as in the attempt of Germany to separate England and France and to intimidate France. As before, this had the natural result of strengthening the union between France and England, and taking a stage further the military and naval accompaniments of this agreement.

*Great Britain and Germany, 1909–14.*—The final settlement of the Moroccan question led to an improvement in the relations between Great Britain and Germany. One of the first acts of Bethmann Hollweg, who on the resignation of Prince Bülow became Chancellor in 1909, had been to make proposals which might bring about an amelioration of the relations between Germany and England, and for the next four years conversations with this object continued. The negotiations turned on two points: (1) a naval arrangement, the object of which would be to prevent the two countries continuing on an unlimited rivalry of armaments; (2) a general political understanding by which each country should be assured that the other would not join in attacking it in case of war. From 1909 to 1911 the discussions took the form of conversations of the ordinary diplomatic nature, interspersed with public speeches in the two Parliaments. They were broken off in the summer of 1911 owing to the Agadir difficulty, but after that had been surmounted, were resumed at the beginning of 1912, when on Feb. 9 Lord Haldane was, in consequence of a suggestion from Germany, sent on a special mission to Berlin. On neither point did these negotiations lead to any definite result. As to the naval agreement it seems clear that Bethmann Hollweg would have welcomed it, but that his support was not strong enough against the opposition of Tirpitz and the Emperor. The proposals for a general political agreement broke down because, as soon as a precise formula was put forward, it appeared that Germany would not be satisfied with any arrangements except one which would be so worded as to imply that Great Britain would be debarred from coming to the assistance of France if she were attacked. Anything of this nature was of course out of the question, for, as Sir Edward Grey said on Nov. 27 1911, "one does not make new friendships worth having by deserting old ones." What Lord Haldane suggested was a statement that: "England declares that she will neither make nor join in any unprovoked attack upon Germany. Aggression upon Germany is not the subject and forms no part of any treaty, understanding or convention to which England is now a party, nor will she become a party to anything which has such an object." What Germany asked for was a statement that: "If either of the high contracting parties becomes entangled in war with one or more Powers, the other party will at least observe toward the Power so entangled benevolent neutrality, and will use its utmost endeavour for the localization of the conflict." This, of course, could not be accepted. None the less, the very fact that this attempt had been made, though it failed, left the relations between the two Governments more cordial; even more important was the practical illustration afforded by the subsequent Balkan troubles as to the importance of coöperation between them. Everything tended to show that the peace of Europe could be maintained if Germany and Great Britain, while each maintaining full loyalty to its own associates, were willing, when any difficulty arose, to communicate frankly and freely with one another and to discuss the best method of settlement. By this means the two alliances might cease from their rivalry and gradually be merged in a general concert. This was a system which Sir Edward Grey deliberately adopted; the whole handling of political difficulties was based upon this, and so long as Germany acted in a similar spirit things went well. When the World War ultimately broke out, it was because Germany, in a very grave crisis, ceased this coöperation and in profound secrecy made herself the associate of schemes the success of which would have been most detrimental to one of the partners in the Triple Entente. Meanwhile, during 1913 and the first half of 1914, negotiations were begun and carried through to a successful issue by which the two chief outstanding points of controversy were in fact removed. A settlement was at last brought about with regard to the Bagdad railway and the reversion of the Portuguese colonies in Africa.

The situation in Germany was, of course, the subject of the most careful study by those who were responsible for directing British policy. Opinions were much divided in England; there was even a belief, which was probably well founded, that neither Herr von Bethmann Hollweg nor Herr von Jagow desired anything but the best relations. On the other hand, it must remain a matter of comparative indifference whether in any particular year the German administration then in office was well disposed. Their position was at the best very precarious. All information, both from public and confidential sources, showed that a very large section of educated German public opinion was animated by feelings of intense animosity against England, and although this party was at the moment in opposition to the Government, at any time they might come into office, all the more because of the very unreliable character of the Emperor, of whom the only thing that could be said with certainty was that no one could foresee what he would do. Moreover, there was another factor to be kept in mind. Good relations between Great Britain and Germany might be valued, not for their own sake, but merely as a device for separating Great Britain from her associates. It was an obvious policy to encourage a spirit of conciliation, so that if there was a serious conflict with Russia, English public opinion would refuse support to Russia. To put it brutally, Germany had no reasons to fear a war if England stood out; according to all instructed German expectations the crisis of any great European war would be over in the first two months. All that was necessary then was to secure that England should remain neutral during the first stage; if once the essential victory in France were secured, then nothing else

really mattered. Germany would quite well be able to acquiesce in an interference of Great Britain at a later stage, for, though this might be used to moderate the claims of the victors, it would not eliminate the fact of the victory. It was the consciousness of this which made it absolutely necessary that every advance to Germany should be accompanied by the clearest and most public intimation that the union of the Entente was not thereby weakened. So we get the key to British policy: the maintenance of the two alliances, but the frank and friendly discussion between Great Britain and Germany on each point of difference as it arose.

This was a policy which required great skill, firmness and a cool head. For this reason, in the very critical circumstances, the direction of British policy was kept to a large extent in the hands of a small group—Sir Edward Grey, Mr. Asquith and Lord Haldane; just as it had been recognized that foreign policy should be kept out of the ordinary party conflict, so it became necessary not to allow vacillation to arise from the conflict of opposed groups in the Cabinet. It was, as subsequent events were to show, a misfortune that some of the other countries concerned were not guided with equal skill and firmness.

*Austria and the Balkans.*—It is not in the stronger but in the weaker states that the occasions for war arise—not in Germany, France and England, but in Russia, Turkey and Austria-Hungary; for when a Government is weak, popular passions have their way, and the best plans of the wisest statesmen may be frustrated. As the long reign of the aged Emperor Francis Joseph of Austria was nearing its end, the whole internal fabric of his empire was growing out of joint, and there was neither purpose, skill, nor foresight to remedy this. As will often happen in such circumstances, there were many who hoped to find in a spirited foreign policy an escape from internal difficulties. One party, reverting to the older Austrian traditions, looked to a war with Italy, for it was a peculiarity of the situation that, while Italy and Austria were allies, they were always arming and intriguing against one another, and the Government of Trieste, by its strongly anti-Italian acts, fomented the spirit of irredentism which had only for a time been suppressed during the first years of the Triple Alliance. But it was the Slav problem which presented the greatest difficulty, and this had both its internal and its external aspect. At home the settlement of 1868 had given to Germans and Magyars constitutional predominance in the Dual Monarchy which was not justified by their numerical proportion. The strong Slav spirit found expression in the growing ambitions of the Czechs, while the southern Slavs, Croats and Serbs alike were in open opposition to the misgovernment of Budapest. At the same time the Magyars, with singular blindness, refused to take any steps to remedy the just grievances of the Rumans of Transylvania. This national discontent when suppressed at home naturally turned for help abroad, and the internal dislocation of the Habsburg Monarchy became involved in the Balkan troubles. From 1894 there had been a cessation of the secular rivalry of Austria and Russia; Russia was occupied with her Far Eastern schemes, and the two empires had agreed on the maintenance of the *status quo*, an agreement which was cemented and continued at Mürzteg in 1897. The Austrian position in the Balkans depended upon the alliance with Rumania and an important understanding with Serbia, which had become almost a client state of Austria. The mutual hostility between Serbia and Bulgaria, Bulgaria and Greece, ensured the continued equilibrium. In order to maintain this state of things, the Austrian Government did not scruple to condone, if it did not actually encourage, the assassination of King Alexander of Serbia. But this instrument they lost by the foolish attack upon Serbian commercial prosperity, the beginning of a definite and final rupture, which, as we have seen, led to and was aggravated by the annexations. From this time it was the one object of the Serbian nation to achieve its expansion at the expense of Austria. To Russia the discontent of the southern Slavs of the monarchy was a welcome weapon. In the rivalry of the two empires a new stage had been introduced. Russia, by fomenting Serbian intrigues, might hope to strike a blow at the very existence of the Habsburg Monarchy itself. There was only one method of meeting this, and that was internal reconstruction. This was said to be the object of the heir to the throne, but, in view of the obstinate resistance to be expected from Hungary, nothing could be done during the lifetime of the old Emperor.

This was the state of things when a new and quite unforeseen evolution began in the Balkans.

*The Balkan Wars.*—It had long been agreed that to Italy should fall the reversion of Tripoli. The increasing disorder of the Turkish Empire, the obvious failure of the Young Turks to establish an orderly and civilized government, made it appear that the time for action had come. In Sept. 1911, at the very crisis of the Agadir incident, without previous warning the Italian Government presented an ultimatum to Turkey, and three days later, on Sept. 29, declared war. On Oct. 4 an Italian force landed in Tripoli, which, during the next months, was occupied with the very difficult task of subduing the resistance both of the Arab population and of the Turkish troops. A full year was in fact to pass before, by the victory of Sidi Bibal, the kernel of the resistance was overcome. Meanwhile, in order to force the Turkish Government to agree to a cession of the province, the Italian fleet in Feb. 1912 appeared before Beirut, and in May occupied Rhodes and the islands of the Dodecanese. It was clear that an Italian attack on Turkey in the Aegean would arouse the hopes and ambitions of the Balkan States themselves. There were abundant causes of trouble. The Young Turks had no more succeeded in bringing peace and order into Thrace and Macedonia than had the Government of 'Abdul Hamid; the religious rivalry, the exploits of the Comitadji, the massacres and ravages by the Turks, continued in this unhappy country, and it seemed as though it were becoming the declared policy of the Turkish Government to remove the Macedonian difficulty by the extermination of the inhabitants. Experience had shown them that no serious help would come from the Great Powers, who, fearful of the consequences of Balkan troubles, adhered with what we may call unintelligent obstinacy to the doctrine of the *status quo*. If anything was to be done, the Christian States must do it themselves. In Feb. 1912 negotiations were begun under the deepest secrecy between Serbia and Bulgaria, and on March 13 there was signed a treaty of friendship and alliance, by which the two kingdoms mutually guaranteed to one another their political independence and the integrity of their territory, and agreed to support one another with all their forces if either were attacked by one or more states. More than this, they agreed to support one another if any of the Great Powers attempted to occupy any part of the Balkans which was at present under Turkish dominion, a clause which was obviously directed against Austria. This treaty was accompanied by a secret additional treaty and a military convention; the first of these was in fact in the nature of an offensive alliance against Turkey and was followed by detailed arrangements as to the disposal of any Turkish territory which might be acquired. The treaty was to be communicated to Russia, and all matters undetermined in the treaty were to be settled by the arbitrament of Russia. The military convention determined precisely the nature and character of the help to be given in the case of a war with Turkey or with Austria or Rumania. This treaty was in accordance with the agreement submitted to the Russian Government, but they did not communicate it to their allies. It was followed in May by a similar treaty between Greece and Bulgaria, the initiative to which was to a large extent given by Mr. J. D. Bourchier, the well-known correspondent of *The Times*. The whole scheme was one unparalleled in recent years; the Balkan States, so long the clients and the playthings of the Great Powers, had at last agreed on that which no one who knew their mutual animosities had believed possible: they had joined together to free their co-religionists from the Turks and if necessary to protect the Balkans against the external aggression of any Great Power.

The action prefigured in the treaties was hastened by the conclusion of the war between Turkey and Italy; negotiations were entered into during the month of August and were brought to a conclusion by the Treaty of Lausanne signed on Oct. 18, by which Turkey surrendered Tripoli to Italy, the future of the Aegean

Is. being reserved for later arbitration. It was necessary, if the attack on Turkey were to be made, that it should take place at once so as not to leave time for preparation. On Oct. 8 Montenegro declared war; on the 13th the three other allied states presented an ultimatum demanding the immediate grant of autonomy to Macedonia; on the 14th the population of Crete declared themselves independent of Turkey, and formally joined Greece; and on the 17th the declaration of war was sent.

These events seem to have been carried out without the privity of any of the Powers except Russia, and were equally unwelcome to all—to the Entente as much as to the Triple Alliance. At the last moment a hasty and ill-advised scheme was put forward by the joint action of Austria and France for localizing, if not preventing, the impending hostilities; the united Great Powers of Europe declared that in the event of hostilities they would not permit any alteration of the territorial status. At least German opinion seems to have anticipated rapid success for the Turks, a success which would have been welcome to them; they were speedily disappointed and disillusioned. Before the end of the month the Turkish army had been defeated and routed by the Bulgarians in the two great battles of Kirk-Kilisse and Lule-Burgas; the Serbians had overrun the whole of Macedonia, the Turkish force opposed to them fleeing in panic and disorder. The Greeks, advancing from the south, occupied southern Albania and also quickly made their way to Salonika. Within a month the Turkish rule in the Balkans had come to an end; there was left to them only Constantinople and parts of Thrace. The Bulgarians advanced rapidly towards the capital; it was for the moment their dream that it would be a Bulgarian army which would rescue San Sofia from the Moslems, and Ferdinand hoped that the day was approaching when he would ride as a conqueror into the streets of Constantinople. They were disappointed. In a series of battles, Nov. 17–22, the Bulgarian assault on the lines of Chatalja failed; cholera made its appearance in the army and on Dec. 3 an armistice was concluded.

It remained for Europe to determine its attitude towards these unexpected events. The danger was extreme that the Balkan might become a European war.

The Austrian Government was determined to put a barrier to Serbian ambition. The arrangements with Bulgaria were based on the assumption that Serbia should gain her reward by the annexation of the northern part of Albania and should thereby obtain access to the Adriatic. This Austria would not permit. She did not wish to see a Slavonic State having access to a sea which she looked upon as her own. In this matter she could depend upon Italian support. Austrian troops were mobilized; garrisons in Herzegovina were placed upon a war footing, and the situation was aggravated by numerous personal incidents, as for instance by stories which were put about that the Serbians had imprisoned and ill-treated an Austrian consul. War between Austria and Serbia was imminent, but if it broke out Serbia would be supported by Russia, and in answer to Austrian military preparations, Russian troops on the south-western frontier were placed on a war footing. A war between Austria and Russia would, in consequence of the complicated system of alliances, inevitably bring in Germany and France, and thereby bring about the great struggle which everyone wished to avoid. The danger was averted by France, Great Britain and Germany, who worked together to bring about conciliation. It had been arranged that, side by side with the peace negotiations which were taking place in St. James's Palace, the ambassadors of the Great Powers in London should sit in conference under the presidency of Sir Edward Grey. It was agreed that France and Great Britain should give their support to Austria, and that Albania should be set up as an independent state. This removed the essential point of controversy, and in February the Austrian Emperor sent Prince Hohenlohe on a special mission with a letter to the Tsar. It was agreed that the two Powers should demobilize, and from this time the extreme friction began to diminish. But the refusal of Serbian access to the Adriatic was to have unexpected results. It cut away the basis on which the division of the spoil had been arranged between the Balkan States. The Serbian Government therefore demanded a larger portion of Macedonia than had been originally assigned to her. They based this claim also on the point that Bulgaria had not provided her due share of forces to fight in the western area, while Serbia had contributed more than she was bound in the struggle for Adrianople. Under these circumstances an appeal to the Tsar to arbitrate was enjoined. But before he had even received the appeal, a catastrophe took place. The old animosity against Bulgaria, which had been for so many hundreds of years traditional among the Greeks and Serbians, was again growing. The armies were in Macedonia still in closely adjacent quarters. The Bulgarian Government, under what influence we do not know, determined on a sudden blow, and on June 29 an attack in form was delivered by the Bulgarians against the Serbian forces. Immediately afterwards the Greeks in Salonika attacked the Bulgarians. This new fratricidal war had scarcely begun when two new champions entered the field. The Turks denounced the armistice and a fortnight later retook Adrianople. On July 18 Rumania, with a fresh army, entered the field, declared war on Bulgaria, and occupied the Dobruja. Before this great superiority of force the Bulgarians, who had lost so heavily in the war—the dead alone were 30,000—had no course open but to capitulate. On the demand of Rumania a conference was summoned to Bucharest, which on July 30 arranged an armistice, and on Aug. 11 the Peace of Bucharest was signed. By this Bulgaria had to surrender to Serbia the whole of Macedonia, to Greece a large part of the northern shore of the Aegean, while to Turkey she had to restore Adrianople and to Rumania to surrender the Dobruja.

The situation left by the Treaty of Bucharest was very precarious. It was obvious that Bulgaria would not willingly acquiesce in the loss of territory and prestige. The mutual animosity between Serbia and Austria continued, and the Prince of Wied did not show himself capable of coping with the very serious difficulties in Albania. There were acute differences between Turkey and Greece, and the renewal of war seemed imminent. But these mere local complications could doubtless have been overcome so long as no one of the Great Powers intervened; separate action by any one of them must almost inevitably bring about the great trial of strength between the rival alliances. It was the object of every responsible statesman to prevent this arising. The immediate danger arose from Austria and Russia. Austrian policy was inclined towards Bulgaria and desired to see the Treaty of Bucharest overthrown. In the summer of 1913 they proposed an immediate attack on Serbia; in this they did not have the support of Berlin. The German Government was clearly dissatisfied with the Austrian handling of the Serbian difficulty, and also with the unneccesary harshness with which the Hungarians treated the Rumans. They rightly saw that an amelioration of the position must be found in an internal reform of the Dual Monarchy. On the other hand, German ambitions were becoming a serious danger. Count Wangenheim, who had succeeded Marschall von Bieberstein as ambassador to the Porte, was with great assurance strengthening the German control at Constantinople. This was a development which Russia could not regard with equanimity. A crisis was reached during the winter, when Gen. Liman von Sanders was not only appointed to reorganize the Turkish army, but was given actual control over the army corps stationed in Constantinople. This led to a strong protest from Russia, and was followed by very violent press polemics between Germany and Russia. It is clear that Russia was becoming impatient. It looked as though Germany, with the conclusion of the Bagdad agreement, and in other ways, would gain complete control over Turkey, military, political and economic. This, if achieved, would be a formidable impediment to the ultimate realization of what had for so long been the permanent object of Russian policy—not only the opening of the Straits but the control of Constantinople. In February, as we now know, the situation was reviewed; it was agreed that these hopes could only be achieved as the result of a European war, and that it was necessary to prepare the scheme for landing troops on the Bosporus if the contingency arose. Russia did not take her allies into her confidence. The most serious

element in the situation was that, more and more, the old rivalry between Austria and Russia, which had always been found manageable, was giving place to a direct conflict of interests between Russia and Germany herself. So long as Austria alone was concerned, it could be hoped that Germany, who had no desire to embark on a European war merely in defence of the local Austrian interests, would intervene in some way or another and join with England in keeping the peace. So soon as the direct ambitions of Germany herself were involved, this security was removed. Moreover, the commercial treaty made between Russia and Germany in 1892 was running out; Germany had succeeded in imposing upon Russia conditions which subordinated Russian interests to those of Germany. Any negotiations for the renewal of the treaty must certainly react on the political situation. Already the very anticipation of this had aroused all the strong national spirit in both empires. The Russians in particular were determined not to anticipate a renewal of the humiliating position in which they had so long been placed.

The preceding narrative will have shown how complex was the diplomatic situation. But after all, this was nothing new in the history of Europe, and the points at issue in almost every case concerned not the vital security of any one of the Great Powers, but rather the external extension of their power and influence. It might therefore well have been hoped that, with prudence and self-restraint on the part of the leading statesmen, peace might be kept. Experience showed that a solution could be found for each particular problem as it came up, either by separate negotiations between the interested Powers, or by substituting for the mutual rivalry of two hostile groups common action of the Concert of Europe. This was the principle by which Sir Edward Grey was always guided, and it was his hope that in it he might have the support of the German Government. It was a policy which could only be successful if it was accompanied by a frank recognition of the existing facts, with the avoidance of subterranean intrigues.

*The Rivalry in Armaments.*—So long then as England could depend on German coöperation, war might well have been avoided had the trouble been merely diplomatic. There were, however, other elements. Diplomatic controversy was accompanied by the rivalry in armaments. European Ministers of War were ceaselessly occupied in perfecting the armies. The continued expansion of German population enabled this to be done within the limits of the Law of 1871, which determined that the strength of the army on its peace footing should be 1% of the population. In 1893, by reducing the term of service from three to two years, the number of trained men was increased by nearly 50% without any increase in the peace establishment. Further increases in the peace establishment were made in 1899, in 1905 and in 1911. In 1912, after Agadir, the establishment was raised to 723,000. The Balkan wars, ending as they did in the collapse of Turkey and the increased power of Serbia, were made the reason for a still further addition. The peace strength was raised to 870,000 men, and to meet the extraordinary charges involved in this the Government had recourse to the dangerous expedient of a capital levy of £50,000,000. Each of these laws was of course answered in France and in Russia, and in 1913 France, always confronted by the fundamental disadvantage of her smaller population, had no resource except to raise the period of compulsory service with the colours from two to three years. It was obvious that this state of things could not continue. The strain on the finances and on the manhood of the nations was becoming overwhelming. But when it was proposed that the limitation of armaments should be discussed at the Hague Conference in 1907, it was Germany who answered that she could take no part in any conference where this matter was on the agenda. At the same time the general staffs were planning in detail every step in the campaign. To Germany the "war on two fronts" had become a household conception. All the details were worked out by Schlieffen—the instantaneous blow on France which must be delivered and carried through before the more slow-moving Russian battalions were on their way. But if this blow was to be successful it must be delivered not on the guarded frontier to the east, but across Belgium. And so all the preparations were made, the lines were built, military camps established, the dislocation plans worked out. This could not be hidden. France had to devise her counter-moves to the opening gambit. If the war began with an unprovoked attack by Germany, then the French hoped they would not be alone; they could depend on the coöperation of Great Britain and Russia. But this coöperation would be futile unless it had been planned in advance. The safety of France would depend upon the promptitude of her allies. The mobilization of Germany would be almost instantaneous. That of Russia must be accelerated, and every detail be prepared for placing the army on the frontier at the earliest moment. Hence we get the building of strategic railways in Poland and a great reorganization of the army. But this again was represented in Germany as a menace, which was made a reason for further increases in the German army. The effect was felt even in the most unmilitary of nations. Belgium, whose security was once more threatened, had to introduce compulsory military service, and Great Britain could not stand out. The war when it came would not move with the deliberation of the great collisions of earlier days when it was sufficient for Great Britain to begin to collect an army after the first shot had been fired. Whatever the course of events might be, one thing was clear to everyone—the result would be determined to a large extent during the first six weeks. If, as seemed probable, the war began with the German invasion of Belgium, then British troops must be there to protect the soil of Belgium and of France. Therefore, as early as 1906, Sir Henry Campbell-Bannerman approved the conception of conversations between the general staffs to discuss the forms of coöperation in the event of war. But if this coöperation was to be effective, the British army must be ready. And so a great reorganization took place, carried through by Lord Haldane as Minister of War, the result of which was that, for the first time in her history, England would at the outbreak of the war be able, if necessity required and the occasion justified it, to place some 150,000 men in the north of France before the first contact took place; in 1912 the agreement as to military conventions was embodied in an interchange of notes between England and France.

*German Militarism.*—The rivalry in armaments and the inordinate growth of the armies had a double effect. It directly influenced the diplomatic discussions. Neither side could avoid the apprehension that their opponents might be deliberately intending to force the issue; as soon as this apprehension arose, then military preparations must begin, even while diplomatic discussion was continuing; but the very suggestion of this would at once bring the general staffs into the discussion. They, intent only on ensuring that, if there was to be war, nothing should be left undone which would secure victory, might easily divert the negotiations which normally had as their object the avoidance of war, and substitute the object of bringing about war at a favourable moment and under favourable auspices. Much therefore depended on the submission of the military to the political element. This was completely secured in those western democratic states in which the control over the Government lay in the hands of Parliament; the situation was less favourable in the three eastern monarchies—in Russia, where a weak ruler and an incompetent and dishonest bureaucracy were struggling against the rising forces of revolution; in Austria, where conflict of nationalities threatened the very existence of the state; in Germany, where it was the official doctrine taught by Bismarck, the theme of every speech of the Kaiser, that the power, the influence and the existence of the nation were based upon the army. The world was never allowed to forget that if Germany was now the greatest Power in Europe, it was because the German army had marched to Paris in 1870, and, if necessity arose, could do so again; and the German people were never allowed to forget that it was the Prussian army by which German unity had been achieved, and it was on the army, carried out with the spirit of and trained by Prussian officers, that the existing constitution depended. The influence of the German Emperor ultimately depended on the prestige which he had inherited,

and, if the crisis came, he could only maintain his power by the same methods by which it had been attained.

It was in Germany and Germany alone that organized and official opinion put forward, as the very basis of political life, frank and unabashed, the power of the sword. Historically this could easily be explained, and no nation can free itself from its own past. English opinion, just because it required the maintenance of sea-power, on which the existence of the Empire and the security of the nation depended, was always prompt to recognize the equal necessity to Germany of a strong army. But it could not be obscured that, while in other nations the maintenance of great armaments was regarded as a burden of which they would gladly be freed, in Germany the increase of military power was welcomed as an end in itself. It was not merely a weapon of security, an instrument of Government—it was the basis of the state; the efforts of the pacific writers were not merely criticised on their merits, but condemned as heresy. And this was no mere academic principle—it was made the corner-stone of German diplomacy. Whatever the question at issue might be, always there was heard from Germany the ultimate appeal to the German army. This bred a habit of impatience. Whenever Germany was worsted in diplomacy—and this often happened—there were many who would cry out that after all there were other means by which she could secure the victory.

Every increase in German armaments required an appeal to the patriotism of the people. These appeals could not be made without arousing a dangerous spirit. The German Government had been glad to secure the support of the newly formed *Flottenverein* for their great naval programme; its emissaries found their way into every town and village in the country, and the literature they disseminated necessarily encouraged hostility to Great Britain. The Pan-German League openly advocated a policy which would have involved Germany in war with every country in the world, but the rising spirit of Chauvinism had spread far more widely, and the very fact that it was criticised by the Socialists tended to make sympathy with it the hallmark of a "good German." The Government, which depended for the naval and military votes on the spirit of militant patriotism, found that they had aroused a force which they could not, even if they would, control. During the year 1913 the centenary celebrations of the great events by which Germany freed herself from the Napoleonic yoke added fuel to the flame. Inspired by the intense consciousness of Germanic superiority, the Germans were ready, when the time came, to emulate in war, as they had surpassed in peace, the deeds of their forefathers.

BIBLIOGRAPHY.—*Official documents and publications:* The texts of the treaties will be found in British and foreign state papers. The most important special collection of treaties is: Dr. Pribram, *The Secret Treaties of Austria-Hungary 1879–1914* (1920). The text of the Franco-Russian agreement is published in *Documents diplomatiques: L'Alliance Franco-Russe*, issued by Ministère des Affaires Étrangères (Paris, 1918). The treaties between the Balkan States in 1912 were published by Guechoff in *L'Alliance Balkanique* (1918); *see* also BALKAN PENINSULA: Balkanicus, *The Aspirations of Bulgaria; Report of the International Commission to inquire into the Causes and Conduct of the Balkan Wars* (Carnegie Endowment, 1914); *Le Traité de Bukarest* (Bukarest: Imprimérie de l'État, 1913). The official statement of the German case on the responsibility for the war, *Das deutsche Weissbuch über die Schuld am Kriege* (1919), contains a good deal of material, especially on the relations with Russia and Balkan affairs. Siebert, *Diplomatische Aktenstücke zur Geschichte der Ententepolitik der Vorkriegsjahre* (1921), appeared too late to be used in this article. The fullest general treatment of the period is that by Reventlow, *Deutschlands Auswärtige Politik 1888–1913* (1914). The second edition, 1915, differs materially from the first. Egelhaaf, *Geschichte der neuesten Zeit* (1918), is a well-arranged textbook, but the treatment of the events connected with the war is very partisan. The fullest treatment in English is that of Bernadotte Schmitt, *England and Germany 1740–1914. Zur Europäischen Politik 1897–1914: Unveröffentlichte Dokumente in amtlichem Auftrage herausgegeben unter Leitung von Bernhard Schwertfeger*, 5 vols., contains selections from the despatches of Belgian diplomatists during the years before the war, which were taken from Brussels during the German occupation.

For British policy before the war, see Lord Haldane, *Before the War* (1920); Lord Loreburn, *How the War Came* (1919); Sir E. Cook, *How Britain Strove for Peace;* Prof. Gilbert Murray, *The Foreign Policy of Sir Edward Grey;* Sir Geo. Prothero, *German Policy before the War* (1916). The correspondence between the German Emperor and the Tsar has been published in *The Kaiser's Letters to the Tsar* (The Willy-Nicky Correspondence), edited by N. F. Grant.

Among the memoirs and reminiscences the more important are: Prince v. Bülow, *Imperial Germany* (1914); Grand Admiral v. Tirpitz, *My Memoirs;* Karl Helfferich, *Die Vorgeschichte des Weltkrieges* (1919); Bethmann Hollweg, *Reflections on the World War* (1920); von Jagow, *Ursachen und Ausbruch des Weltkrieges* (1919); Baron Beyens, *L'Allemagne avant la Guerre* (1915); Dr. M. Boghitschewitsch, *Kriegsursachen* (1919), (English translation, C. L. Van Langenhuyen, *Causes of the War*, 1919); Raymond Poincaré, *Les Origines de la Guerre* (1921); Baron v. Eckardstein, *Lebenserinnerungen und politische Denkwürdigkeiten* (1919). Of great importance are the four volumes by Otto Hammann: *Der neue Kurs, Zur Vorgeschichte des Weltkrieges, Um den Kaiser* and *Der missverstandene Bismarck.*

For the growth of the German navy see Archibald Hurd, *The Command of the Sea* (1912); for Austria-Hungary: H. Wickham Steed, *The Growth of the Habsburg Monarchy* (4th ed., 1919); Dr. Seton-Watson, *The Southern Slav Question and the Habsburg Monarchy* (1911); for Morocco: Caillaux, *Agadir* (1919); Tardieu, *La Conférence d'Algeciras* (1907); E. D. Morel, *Morocco in Diplomacy* (1912, republished as *Ten Years of Secret Diplomacy*, 1920); *Documents Diplomatiques: Affaires du Maroc* (1912). (J. W. H.-M.)

### THE OUTBREAK OF WAR

*The Murder of the Austrian Archduke.*—The preceding pages of this article describe the state of Europe when, on Sunday, June 28, the Archduke Franz Ferdinand, the heir to the Austrian throne, and his wife, while on an official tour of inspection in Bosnia and Herzegovina, were murdered at Serajevo, the capital. The two assassins were young men of 20 years of age, natives of Bosnia and therefore Austrian subjects. Such evidence as is available seems to show that the motive for the crime must be traced to the intense racial animosity which had existed in Bosnia since the time of the annexation, increased as it was by the growing discontent in Croatia, and by the rising tide of aggressive nationalism in Serbia; no evidence has been forthcoming which would compromise any responsible Serbian officials, still less the Serbian Government itself. Among the accomplices were indeed two residents of Serbia, a major named Jankasitch and a Croatian exile, Tziganovitch, the first being a Comitadji chief, the second a temporary railway clerk. All the other accomplices seem to have been Bosnians. The two assassins were eventually condemned to penal servitude; of the accomplices three were executed. This crime created a great sensation. It happened at the time of the German festivities at Kiel, associated with the completion of the enlargement of the canal, at which a British squadron was present. They were at once broken off. The German Emperor returned to Berlin. He intended to go to Vienna to attend the funeral of the Archduke, and at the same time to discuss the political situation with his ally; this project was abandoned, for the police had intelligence of a great plot; twelve assassins were on their way to Vienna.

Elsewhere, except among the comparatively few who really understood how precarious was the position in the Balkans, it was the personal aspect of this event which attracted attention. The general feeling was one of deepest indignation, and of the warmest sympathy for Austria and for the aged Emperor, Francis Joseph, whose life had already been so full of tragedy. In Austria it was regarded as a grave political portent. The death of the Archduke seems to have been treated in the highest quarters with remarkable equanimity, but the crime which was no isolated act was looked on as a blow at the very existence of the monarchy. The relations with Serbia had for long been the cause of grave disquiet, internal as well as external. There had in fact just been drawn up a very important Austrian memorandum for communication to the German Government; in it the Balkan situation was discussed, and stress was laid on the scheme attributed to Russia of creating a new Balkan league, which was to include Rumania and be used as an offensive weapon against the Triple Alliance. In this scheme the disaffection in Bosnia and Croatia, which was fermented by the agitation from Serbia, would be a dangerous instrument. Against this it had been intended to propose a pro-Austrian anti-Serbian alliance with Bulgaria and Turkey, which could be used also to check the pro-Russian influences in Rumania. Count Berchtold and his col-

leagues now determined immediately to use this new opportunity so as to rid themselves once and for all of the menace to the monarchy caused by the Yugoslav propaganda; by doing so they would be bringing to an issue, on an occasion favourable to themselves, the great rivalry in the Balkans with Russia.

The policy of Count Berchtold was apparently influenced by three motives: (1) the quite justifiable determination for the punishment of the murderers and their accomplices, together with the prevention of similar acts in the future; (2) the desire to show that the Austro-Hungarian Monarchy was not effete, helpless and incapable of action; (3) to gain a great and permanent political advantage as against Russia. Of these the second seems to have been the most important. There was a general feeling throughout the empire that the Government must show its strength by some strong act, a feeling which was encouraged by the language used by the German ambassador in Vienna: "What Germany looked for was a firm and definite plan of action; if this was forthcoming she would be completely on the side of Austria." But Austria could not take action unless sure beforehand of German support. Count Hoyos was therefore despatched on a special mission to Berlin. He took with him both the memorandum written before the murder and also an autograph letter of the Emperor to the Kaiser of July 2, in which the dangers to Austria of the Serbian agitation for the union of all Southern Slavs under Serbia was pointed out. In view of this the policy of Austria must be the isolation and diminution of Serbia and the suppression of Serbia as a political factor in the Balkans; it was necessary for the peace of Europe that the criminal agitation in Belgrade should not continue with impunity.

*The Decision in Berlin.*—This letter was delivered personally by Count Szögyény, the Austrian ambassador, on July 5 to the German Emperor, who was due to leave for his annual holiday in the North Sea on July 7. It was during these two days that the decision on which so much was to depend was made. The information available up to the end of 1921 as to the actual course of events in this respect still left much obscure. During the war it was circumstantially reported that a joint council was held between Austrian and German statesmen and soldiers at which a plan of political and military action was decided. It now seems clear, however, that no such formal meeting took place, an omission which has naturally been the subject of hostile criticism in Germany; the very serious diplomatic steps which were to follow ought undoubtedly to have been preceded by a thorough sifting of the whole situation—political, military, naval and economic. The Kaiser, after receiving Count Szögyény and Count Hoyos before he left for Norway, had, as he could not well avoid having, separate conversations with representatives of the army and navy. It is beyond doubt that the final decision was one for which he was immediately and personally responsible. While explaining that he must, of course, consult the Chancellor on a matter of serious European importance, the Count was authorized to inform the Austrian Emperor that in this question he could "depend on the complete support of Germany." "This especially applied to Austrian action against Serbia." "In the Kaiser's opinion there must be no delay. Russia's attitude would certainly be hostile, but he had for years past been prepared for this; if it was to come to a war between Austria-Hungary and Russia she could be convinced that Germany would stand at her side with her usual fidelity. Moreover, Russia, as matters stood, was in no way ready for war, and would certainly consider before appealing to arms." This is confirmed by the diary of Herr Mühlon and the comments on it by Herr Helfferich, from which we can gather that those who had been brought into contact with the Kaiser understood that he was determined that on this occasion there should be no drawing back; his support would be given to Austria, and Austria would be sure that he would continue it to the end; he was especially urgent that Austria should act quickly; delay would increase the risk of a European war.

The Kaiser left Berlin for his visit to Norway, as arranged, on July 7. The official German answer, though more guarded, was in accordance with his language. In it the Chancellor explained that the view of the German Government was that the relations between Austria and Serbia were a matter within the competence of Austria alone; Germany therefore did not propose to claim any right to interfere. What this, of course, meant was that Austria received a free hand to couch her demands on Serbia in such terms as she chose; Germany already knew that they would be such as to make war very probable. But Austria had already been assured that, if this action led to war with Russia, Germany would be at her side. It is noticeable that no advice or warning was given that the demands on Serbia should be so modified as to avoid this danger. On the other hand great attention was given to the diplomatic preparation; everything was to be done to secure for a war with Serbia the support or neutrality of the neighbouring states. With this object the Kaiser, though strongly against his own personal inclination, agreed that the King of Bulgaria should be asked to join the Triple Alliance, and, in view of the great German interests in Turkey, negotiations with the same object should be entered into with the Porte. What above all interested them was the position of Rumania and Italy. The situation in Rumania caused much anxiety, for King Charles let it be known that he would probably not be able to bring the country with him into a war with Russia on the side of the Germanic Powers; all, however, was to be done to strengthen German influences in that country. As to Italy it was agreed that its Government should not be informed beforehand as to the blow which was impending against Serbia, but Germany pressed very strongly that Austria should be prepared to offer to Italy suitable compensation for any gain in territory or political influence in the Balkans which might accrue to her.

Analysis of the objects and motives of the German Government is all the more difficult because, in its political composition, it had no powerful personality such as Bismarck had once been, and its actions were the result of many conflicting influences, while decisions were always liable to be deflected by the impulsive and vacillating character of the Kaiser himself. There was in the first place genuine indignation at the crime of Serajevo, an indignation which in the Kaiser's mind took the characteristic form that there must be coöperation between all monarchical States against elements of disorder. This motive was one which, no doubt, it was hoped when the time came he would use with effect upon the Tsar. Politically there had long been dissatisfaction at Berlin with the conduct of affairs in Austria; the force and decision which were needed in an ally were wanting. It was hoped, therefore, that the opportunity would be used to remedy this defect. But there were further and greater objects which would follow automatically; if Russia could be persuaded to stand aside while Serbia was overrun by the Austrian army, it would become evident that Russian protection was of no avail to Serbia; Serbia would be pushed out of the way, and thereby the Germanic Powers would gain in fact the control of the Balkans and the road to the East. It was an essential part of the scheme that Great Britain and France should be urged to use their influence to keep Russia quiet; if they did not do so then the responsibility for any extension of the war which ensued would seem to attach to them; if they did then the internal harmony of the Triple Entente would be weakened; Russia would feel that she had been deserted by her allies. It was possible that these results might be obtained without a European war. If, however, Russia was determined to meet the challenge and war resulted, it was hoped that matters could be so arranged that the responsibility for the war should appear to fall on Russia and the Entente. The general condition of Europe was very threatening; it seemed probable that under any circumstances the "great war" must ensue shortly; it was believed that Russia would be ready in about two years. If there was to be a war the summer of 1914 seemed on the whole to be favourable to Germany. The Kiel Canal had been enlarged; the army was at the height of efficiency; the diplomatic situation seemed favourable; there were very serious labour troubles in Russia, serious parliamentary disputes in France, and it appeared as if there might soon be open rebellion in Ireland, with possibly something approaching mutiny in the British army. It was indeed impossible to depend on Italy; but if Bulgaria and Turkey could be won over this would counteract the uncertainty of Rumania's action.

German support having been secured, the Austrian Government proceeded to prepare the text of the demands to be presented to Serbia. The great point was that they should be so drafted that they would be unacceptable; the object was not a mere diplomatic victory but war; it was held that nothing would meet the situation and restore the authority and prestige of the monarchy short of an effective display of military strength. It was agreed, however, in consequence of the strong pressure used by Count Tisza, who alone was in opposition to the policy proposed, that the annexation of any part of Serbia, apart from a rectification of the frontier, should be repudiated; on the other hand, it might well be that, as a result of a successful war, portions of Serbia should be assigned to Bulgaria and Albania. The actual drafting of the ultimatum was apparently entrusted to Count Forgach, formerly Austro-Hungarian minister at Belgrade, who had been closely concerned in the concoction and manipulation of the Friedjung forgeries. On July 17, the final draft, having passed the Council of State, received the approval of the Emperor, Francis Joseph, but it was determined to postpone its presentation till July 23; it would be better to delay until M. Poincaré, the French President, who was to visit the northern courts, had left St. Petersburg.

These arrangements were conducted in the greatest secrecy. All that was known outside was that Austria was contemplating some serious action against Serbia; this was naturally sufficient to cause apprehension and anxiety, but, during the days of waiting, the Austrian Government used its influence to damp down the very violent denunciations of Serbia in the Viennese press, and in other ways tried to still the vigilance of the other Powers. As late as July 19 they assured the Russian ambassador in Vienna that nothing dangerous to the peace of Europe was being undertaken, and in consequence he went on a holiday. The British Government and nation, whose attention was preoccupied at the moment with the Irish problem, were inclined to regard the local dispute between Serbia and Austria as not being one in which they were vitally concerned; and Mr. Asquith's Cabinet, which was perhaps not very well informed as to Balkan matters, was late in realizing how imminent was the danger. On July 16, the British ambassador, Sir Maurice de Bunsen, was able to give Sir Edward Grey a warning which was corroborated from unofficial sources. None the less the belief that there would be a real danger of European war was slow in maturing in Great Britain, in spite of the anxiety felt in a few well-informed quarters. This attitude was based on a belief that, after all, the German Government would not support Austria in any reckless policy.

*The Austrian Note.*—The ultimatum was presented at 6 P.M. on Thursday, July 23, by Baron de Giesl to Dr. Patchou, as M. Pashitch, the Serbian prime minister, was absent from Belgrade. The note had been admirably drawn up to fulfil the avowed object that it should contain demands which could not possibly be complied with. It required that Serbia should first of all officially publish on the front page of the Official Journal a condemnation of the Serbian propaganda against Austria-Hungary, regret for the part taken by Serbian officers and officials in this propaganda, and a promise of amendment in the future. There were in addition ten requirements, which include, among others, the dissolution of "Narodna Obrana," the suppression of any publication which incited to hatred and contempt of the monarchy, the elimination from public instruction in Serbia (including the teaching body) of anything that served as propaganda against Austria-Hungary, the removal from the army and the administration of officers and officials guilty of such propaganda whose names might be communicated by the Austro-Hungarian Government, the collaboration in Serbia of Austro-Hungarian representatives for the suppression of the movement against the territorial integrity of the monarchy, and that Austro-Hungarian representatives should take part in judicial proceedings against all the accessories to the plot of June 28 on Serbian territory. A reply was required by 6 o'clock on the evening of Saturday July 25.

As was immediately pointed out by everyone who read this document it would be impossible for the Serbian Government to accept all these demands; no such requirements had ever been directed to a fully sovereign State—in particular the requirement that unnamed officials should be dismissed on the request of the Austro-Hungarian Government, and that Austro-Hungarian officials should take part both in police and judicial proceedings on Serbian soil, was clearly one impossible to be granted. There could be only one conclusion, that Austria intended to force a war with Serbia and that in doing this she had deliberately prepared to meet the opposition of Russia. But it was clear that Austria could not have taken this step without the previous consent of Germany. It was therefore at once concluded that the two Germanic Powers had determined immediately to challenge Russia, and with Russia France, to a great trial of strength. This view was supported by a note which on the following day was delivered at St. Petersburg, Paris and London, in which the German Government announced that they considered the procedure and demands of the Austrian Government to be both equitable and moderate. (It is now known that these words had been written at a time when the German Government did not precisely know what the demands of the Austrian Government would be. It did not occur to anyone outside that the Government of a great State could be guilty of such unparalleled levity; it was naturally assumed that they had seen and approved the text of the Austrian note beforehand, and all their disclaimers were received with incredulity.) The German Government also emphasized their opinion that the questions at issue between Austria and Serbia should be settled by these two States alone, and lastly, they intimated that interference by any other Power would be followed by incalculable consequences. This could obviously mean nothing except that Germany was backing up Austria, would support her even up to a war with Russia, and that a threat was intended to France and Great Britain that, unless they put themselves on the Austrian side and brought pressure to bear upon Russia to withdraw her support from Serbia, a European war would result.

The news reached St. Petersburg just after M. Poincaré had left. The secrecy with which the ultimatum had been engendered, the misleading assurances, the absence of any warning to or consultation with other States, all seemed to point to a deep-laid plot. The reaction was precisely what was to be anticipated. The greatest indignation was expressed and the indignation was genuine. M. Sazonov at once asked for assurance that he should have the full support of France and Great Britain against this unparalleled act of aggression; the only method of avoiding war with Germany was, he said, that Germany should know that she would be confronted by the united forces of the Entente. At the same time Russian military preparations were at once begun; it was decided at a meeting of the Russian Council of State on July 25 that all preliminary steps should be taken and that Sazonov should be authorized to give the signal for mobilization as soon as it seemed to him necessary. Meanwhile a public communiqué was issued that Russia could not remain indifferent to the fate of Serbia. Similar language was used in private and official interviews. It was from the beginning perfectly clear that Russia intended to resist the Austrian scheme, by war if necessary.

In these circumstances much depended on the action of Great Britain. During these days France could do little, for the President and the Foreign Minister were at sea. Russia and France both pressed Sir Edward Grey to declare himself. The situation was a difficult one. He clearly could not, as the Russians asked, give an unconditional promise to join with Russia if war ensued; by doing so he would incur the danger of increasing the influence of the war party which undoubtedly existed at St. Petersburg. Moreover, he would not have the full support of the Cabinet, nor apparently of the country. On the other hand he could not give the promise of neutrality which Germany asked for, nor could he even press Russia too strongly to suspend her military preparations, for, by so doing, he would in fact be giving his support to an act of aggression against a State with which he was in the closest diplomatic agreement. He therefore saw from the beginning that the only possible means of avoiding a European

EUROPE

war was to bring about some form of mediation or conciliation by which time would be gained; then some means might be found of settling the crisis in a peaceful way. For the next five days, supported by France, he pursued this path with energy and resource. In accordance with the practice of the last years he depended on the coöperation of Germany. To intervene directly between Austria and Serbia was out of the question; if Russia became involved the only remedy would be joint action of Great Britain and Germany. He knew that he had the support of Prince Lichnowsky, the German ambassador in London; he hoped for the coöperation of the German chancellor; he did not know how fundamental was the difference between the German ambassador and his Government.

His first suggestion was that Austria should give Serbia more time, and not, as was threatened, break off diplomatic relations if Serbia did not accept all the requirements of the ultimatum by 6 o'clock on Saturday, July 25. This proposal, which was supported by Russia, received no support in Germany, and in fact reached Vienna almost too late. It was at once rejected there. The Serbian answer was actually delivered at the appointed hour on July 25. It was very conciliatory. It went to the furthest possible extreme in compliance; every demand was granted with the exception of two: the dismissal of unspecified officials and officers and the coöperation on Serbian soil of Austrian officials. The Austrian minister, however, at once, in accordance with his instructions, left Belgrade. Sir Edward Grey, however, now began to press for mediation, not between Austria and Serbia, but between Austria and Russia, by the four Powers, Great Britain, Germany, France and Italy. On July 27 he converted this into a firm proposal for submission of the points at issue between Austria and Russia to a conference of the ambassadors in London. This proposal was rejected by the Germans on the ground that they could not ask Austria to submit to what would in fact be an Areopagus of the Powers. They also would prefer separate conversations between Austria and Russia, which Sazonov had meanwhile suggested. One of the reasons for the rejection was, as has since been explained, that they would not trust their own ambassador in London.

The text of the Serbian answer to the Austrian note was received in London on July 27. Sir Edward Grey at once pointed out that this reply could surely be made the basis of negotiations, and pressed that, if Austria continued her intransigeant attitude, it would appear that she was deliberately aiming at war. These representations were fully reported to Berlin by Prince Lichnowsky, who warned the German Government that, if they continued their negative attitude, they would no longer be able to depend upon the neutrality of Great Britain. These representations were without effect. The German Government indeed on July 27 forwarded Sir Edward Grey's proposals to Vienna, but at the same time they informed Count Szögyény, the Austrian ambassador, that they did so merely because they did not wish to alienate Great Britain, and in no way associated themselves with the proposals which they did not wish to see adopted. The negative attitude of Berlin, the apparent refusal to do anything to restrain Austria, inevitably produced the conviction that Germany was no longer working for peace. If this were so there then remained only one means of avoiding war, that Great Britain should give a formal warning that in the event of war she would be found on the side of Russia and France. This was from the beginning strongly urged both at Paris and St. Petersburg; a first step in this direction was the order given to the British fleet (which had been assembled for manœuvres) not to demobilize; this order was made public on July 28.

However, on the morning of July 28, some change became apparent in the German attitude. The Kaiser had returned to Potsdam from his North Sea cruise on the afternoon of July 27. There was at once laid before him the text of the Serbian answer, which, owing to very serious delay, for which the Austrians were responsible, had not reached Berlin until that day. He saw that it left to the Austrians no defensible ground for a declaration of war. "A brilliant achievement; this is more than could have been expected. A great moral success for Vienna, but with it every ground for war disappears, and Giesl ought to have remained quietly at Belgrade. I would never have ordered mobilisation." He therefore, on the morning of July 28, caused to be sent to Vienna a proposal that Austria should be satisfied with the occupation of Belgrade and a defined limit of territory, and should issue her demands from there. This would give to the military feeling of Austria that satisfaction which they might reasonably demand. As was pointed out: "If Austria continues her refusal to all proposals for mediation or arbitration, the odium of being responsible for a world war will in the eyes of the German people fall on the German Government. On such a basis, however, a successful war on three fronts cannot be started and carried through." The weakness of this proposal was that it was based on the assumption that war with Serbia would have begun; but as soon as war began, clearly Russia must mobilize. No settlement could be successful unless it provided for a mutual understanding as to the military measures to be taken on both sides; such an understanding must be made at once and communicated to Russia. The Emperor's proposal assumed that while Austria began a war with Serbia, Russia should cease all military measures. This clearly was impossible.

*Austrian Declaration of War against Serbia.*—Russian mobilization was in fact becoming imminent. The preliminary work had proceeded rapidly; reports came to Germany from all parts of the Russian Empire showing the activity of the preparations. The Russian position never changed. They would not proceed to the next stage until Austria took overt action either by a military advance or declaration of war. As soon as she took either of these steps, Russia would mobilize part of her forces. This contingency was realized on Tuesday, July 28. Austria had issued an order for the mobilization of eight army corps on July 26, and now sent a declaration of war against Serbia in an open telegram to Belgrade. The Austrian Government had informed Germany of their intention to do this the day before, but no warning or suggestion that some delay would be useful was given. Germany in fact was now beginning to experience the results of the very ill-considered language used three weeks before; the Kaiser had insisted then on the necessity for rapid and vigorous action; to press now for moderation and delay would have exposed him to the charge of vacillation which on other occasions his actions had appeared to justify, and from which he had boasted that on this occasion he would be free.

As soon as the news of the declaration of war reached St. Petersburg it was decided that partial mobilization must follow; the German and other Governments were immediately informed. This decision was confirmed when on the same day the Austrians broke off the separate conversations with Russia which Sazonov had suggested, giving as a reason the declaration of war with Serbia, an act for which they themselves were entirely responsible. Even now, however, there was a delay of 24 hours. The next morning news came that the Austrians had begun to attack and were bombarding Belgrade. Further delay seemed impossible. Apparently the Tsar signed the ukase for the mobilization of 13 army corps in the early afternoon of Wednesday, July 28. After doing so he caused Count Pourtalès, the German representative in St. Petersburg, to be assured that it was not his intention to take any threatening measures against Germany, and that mobilization did not necessarily imply war even against Austria. About 7 o'clock that evening Count Pourtalès called on Sazonov, and under instructions from the German chancellor warned him that any further military preparations or mobilisation would involve German mobilization, and that German mobilization meant war. This message was so worded that it seemed to prohibit even partial mobilization against Austria. The German explanation is that it was meant as a friendly warning, but it was taken, not unnaturally, as something in the nature of an ultimatum. The effect was that the order for partial mobilization was that very evening changed into one for the general mobilization of the whole army. There were many reasons for this. Mobilization included also dislocation of the scheme for drawing up the Russian army on the frontier. The whole arrangements for the scheme would depend on whether it was to be mainly a

warning directed against Austria, or whether an immediate war against both empires was imminent. To change from partial mobilization to general mobilization would be an extremely difficult and complicated task. If partial mobilization would, as seemed to be the case, bring about war with Germany, Russia might find herself in an extremely dangerous situation.

Meanwhile there was great anxiety in Berlin. The Government were not well informed as to the intentions of Austria, and answers to telegrams were long delayed. There was also a serious divergence between the political and military authorities. The general staff were becoming very nervous. If there was to be war it was essential that it must begin at once in order that they might gain the advantage which came from their higher stage of military preparation. Every day that elapsed would have the result of enabling Russia to enter the campaign sooner than had been anticipated. On the other hand, from the political point of view, especially having regard to the effect on public opinion in Germany and in Great Britain, it was most important to avoid action which might appear provocative. Matters must be so arranged that the appearance of aggression would fall upon Russia. The whole situation appears to have been discussed in a council which met at the palace at Potsdam that evening. There is no authentic record of the discussion, but from subsequent revelations it is clear that a demand was made by the general staff for immediate mobilization, and was refused. It was, however, determined to make a strong effort to avoid the danger, which was becoming more apparent, of active British intervention in the war; with this object, that very evening between 9 and 10 o'clock, the German chancellor sent for Sir Edward Goschen, the British ambassador, and made him a strong offer for British neutrality. In return for this Germany would be prepared to promise that in the event of a successful war no part of France would be annexed by Germany. This suggestion was, of course, the next day indignantly refused. Scarcely, however, was the interview over when a fresh telegram from Prince Lichnowsky was received, containing a friendly warning from Sir Edward Grey that, if war resulted, England would probably not be able to keep out of it. This produced something like consternation. The negotiations with Austria as to Italy had not been proceeding favourably, and all the information seemed to show that Italian support would *not* be forthcoming. The very same night three additional telegrams were dispatched to Vienna couched in the most pressing and urgent terms, exhorting the Austrian Government not to continue their refusal against all projects of mediation; if they did so they would be dragging Germany into a European war, in which Italy would not be on the side of the Triple Alliance and in which Great Britain would be among the enemies,—a war, therefore, which would be fought under the most unfavourable conditions. It was only by using the last measure, the threat of war, that British influence for peace began to be effective—but too late.

*Russian and German Mobilisation.*—Among the numerous other telegrams sent out from Berlin on this evening was one from the Kaiser to the Tsar, again impressing on him in the strongest terms the danger of mobilization. In consequence the Tsar, shortly before midnight, telephoned both to the chief of the Russian general staff and to the Minister for War, instructing them to alter the determination already arrived at; there is some conflict in the evidence as to whether he ordered the cessation of all measures of mobilization, or merely that partial mobilization should be substituted for general. However this may be, the Minister for War, General Sukhomlinov, who was much impressed by the dangerous position into which Russia was drifting, and by the inextricable confusion which would be created if the mobilization orders which had already been sent out were countermanded, determined on his own responsibility to disobey the orders which he had received and to leave things as they were; and he told the chief of the staff, General Januskevitch, to ignore the Tsar's instructions. In consequence the order for general mobilization was maintained. M. Sazonov does not appear to have known this; anyhow he told the French ambassador that the order for general mobilization had been issued, but subsequently revoked. At a meeting which took place the following morning, July 30, the situation was again discussed, and on this occasion Sukhomlinov, according to his own evidence given at his subsequent trial, "lied to the Tsar" and allowed him to believe that his orders had been executed. During the same morning a further interview between Sazonov and Pourtalès had resulted in the drafting of a formula by which it was hoped that a way out of the difficulty would be found. This had been sent to Berlin. The answer to it came in the late afternoon and was an uncompromising refusal. During the day there was telegraphed from Berlin news of a false press announcement that German mobilization had been ordered; this was contradicted very shortly afterwards. As a result of these events and the information that the Austrian bombardment of Belgrade was continuing, the Tsar in the afternoon reconfirmed the decision of the previous evening that general mobilization should be proceeded with. He seems never to have been informed of the disobedience to his orders. The notices were put up throughout the Russian Empire during the course of the night, and on the following morning the fact was public. There was, however, some delay in communicating it abroad; the news does not seem to have reached either Paris or London until very late in the afternoon. It reached Berlin shortly after midday. The Kaiser at once left Potsdam for Berlin and ordered the proclamation of *Kriegszustand*, the first step before mobilization; a telegram was also sent to Pourtalès that he should immediately call on Sazonov and inform him that unless the order for general mobilization was recalled within 24 hours Germany would consider herself at war with Russia. No answer was given; German mobilization was proclaimed the next day, Saturday, Aug. 1, and war was declared at 5 o'clock in the afternoon.

The Russian order for general mobilization seems on all grounds to have been ill-advised; from the military point of view delay was advantageous to Russia. Politically it provided the German Government with the pretext which was essential to them: for the moment it appeared as if Germany was defending herself against a Russian invasion; the solidarity of the nation was secured and even the Socialists ceased their criticism and opposition. It was this which made the Reichstag, which assembled on Aug. 3, almost unanimous in its support of the war measures laid before it. It also destroyed any slender possibility of still avoiding war. The decision seems to have been due not so much to any deliberate desire for war, as to the state of nervous panic which prevailed in the sinister situation by which Russia was suddenly confronted; owing to the provocative and menacing action of Austria and Germany there was no cool and balanced judgment or strong hand to exercise control. All accounts agree that even Sukhomlinov was overwhelmed by the crisis, and the Tsar throughout was in a state of pitiable indecision.

The extreme rapidity with which these events took place frustrated all the efforts at mediation which were in progress. Sir Edward Grey had put forward a new plan, very similar to the German Emperor's proposal that Austria should issue her terms from Belgrade, but he had accompanied it by conditions which, if accepted, would have got over the mobilization difficulty. This had been communicated by Berlin to Vienna, but no answer had been received when Germany, by her ultimatum, broke through all the negotiations. None the less, even as late as Saturday, Aug. 1, this and other suggestions continued to be the subject of an interchange of telegrams. While they ceased to have any practical importance it may be noted that, in a telegram of July 31, the Austrian Government so far deviated from their previous attitude as to accept the idea of mediation by the four Powers between Austria and Serbia. This was a considerable concession, but it was in fact superseded by a personal telegram from the Austrian Emperor sent almost at the same time, and its value was diminished because it was accompanied by the condition that Austrian military action against Serbia should continue, but that Russia should discontinue all her military preparations. It need not be said that on these lines no arrangement could have been made, for this would have implied that Russia should stand passively by, watching the defeat of the Serbian army and allow-

ing Austria to occupy the whole of Serbian territory. There is indeed no indication that, so far as Austria was concerned, the postponement of the Russian general mobilization would have had any effect upon the final issue. The order for general mobilization was determined on the afternoon of July 30, and issued on July 31, before Russian mobilization was known.

*France and Germany.*—In accordance with the terms of the Franco-Russian Alliance, an aggressive war declared by Germany against Russia inevitably entailed war with France. The French President, M. Poincaré, and the premier, M. Viviani, reached Paris on the evening of July 29; they at once telegraphed to Russia that France would fulfil the obligations of her alliance, while continuing her efforts to preserve peace. From the beginning of the crisis France had, like all other nations on the continent of Europe, immediately begun all the necessary military preparations. Even the smaller States, such as Holland, had from the beginning of the week been doing the same thing. It is not necessary to enter into the discussion which took place at the time as to the particular stage of military preparations reached in each country on each day. The Austrian ultimatum to Serbia was an act of such a nature that, followed as it was by the rupture of diplomatic relations and the declaration of war, no responsible Government could afford to lose a moment in carrying through every measure short of the final act of calling up the reserves, to which the name of "mobilization" is generally given. Suffice it to say that by July 31 the French and German covering troops on the frontier were both in position. The French, however, in order to avoid any untoward incident, took the precaution of keeping their troops 10 km. from the frontier. This was not imitated by the Germans, and in fact could not be, for the great fortress of Metz was actually on the frontier, and there seems no doubt that before July 31, on several occasions, German troops had crossed the French frontier. The Russian mobilization, the consequent German mobilization, and the declaration of war against Russia, made it imperatively necessary for the German Government without any delay to settle the issue with France. As has already been pointed out, the basis of their whole plan of operations was an instantaneous invasion of France. They therefore could not allow a day to pass unused; if there was to be war with France, it must come at once. Accordingly at 7 o'clock on July 31, Herr von Schoen, the German ambassador in Paris, called on M. Viviani and announced that he would come again the next day to learn what the attitude of France would be in case of a war between Germany and Russia. He came in consequence on Aug. 1, and was informed merely that "France would do that which her interest dictated." French general mobilization was ordered on Aug. 1, at almost exactly the same time as that of Germany. It would have been natural that the actual declaration of war by Germany should immediately have followed; it was, however, delayed for two days, partly in consequence apparently of a misunderstanding which arose in London. Lichnowsky telegraphed that he had received an inquiry whether Germany would stand out if England secured the neutrality of France. What seems to have been meant was an idea that both France and Germany should remain neutral, leaving Austria and Russia alone at war; this was misinterpreted as a suggestion that France should remain neutral in a war between Germany and Russia. Nothing could have been more favourable to Germany than this, but subsequent revelations have shown that even French neutrality alone would not have been accepted by Germany. Herr von Schoen was instructed, if France promised to remain neutral, to demand that she should hand over the fortified cities of Toul and Verdun to Germany as a guarantee. That such a proposal should ever have been seriously entertained shows how abnormal was the mentality of Berlin. There was never the slightest doubt that France could not leave Russia unprotected against a combined attack from both Germany and Austria.

The situation at the end of the week was a very anxious one in Paris. War with Germany was now certain, and France might anticipate that within a few days the whole force of the German army would be thrown against the frontier. The future of France seemed to depend upon the action of Great Britain. But in London all seemed uncertain. The strongest representations were made by M. Cambon to Sir Edward Grey, and the President of the French Republic addressed an autograph letter to King George urging the vital necessity for help from England. No promise could be given. The British Cabinet were then divided. Neither they nor, as was thought, the country would have approved of the interference of Great Britain in a continental war in which her interests and honour were not immediately involved.[1] Though Great Britain could not stand by and passively watch the defeat and dismemberment of France, this might be a reason for preparing to intervene if at any time it became necessary, but not for taking part as a principal from the beginning. There was indeed one point in which, admittedly, both British interests and British honour were closely concerned, viz.: the neutrality of Belgium. Great Britain was bound by the Treaties of 1839 to intervene if either party to a war violated that neutrality. Following, therefore, the precedent of 1870 Sir Edward Grey, on July 30, addressed a message both to the French and the German Governments, drawing their attention to this point and asking for assurance that Belgian neutrality would be respected. The answer from France was quite satisfactory. The German Government, on the other hand, said that they were unable to give any answer to the question. On Sunday, Aug. 2, Sir Edward Grey, on his own responsibility, without obtaining the consent of the Cabinet, took another step. He informed the French that if a German fleet attacked France in the Channel or the Atlantic, Great Britain would immediately intervene with her fleet. Apart from the Belgian question, it would still have been possible for Germany to keep Great Britain neutral by limiting the war against France to land operations, and it would clearly have been in her interests to do so.

All then seemed to depend on the Belgian question. On Monday, Aug. 3, the German Government formally declared war against France. The actual reasons given were statements that the French had violated German territory by dropping bombs from aeroplanes, and in other ways. The German Government has since acknowledged that these statements were untrue. Meanwhile it became known in London (Aug. 2) that German forces had crossed the Luxemburg frontier and occupied the Grand Duchy, the neutrality of which was guaranteed by the Great Powers, Germany herself included; and also that the German minister at Brussels (as Sir E. Grey told the House of Commons on Aug. 3) had delivered a note to the Belgian Government demanding free passage for their troops across Belgian territory; if this was granted they undertook to leave Belgium at the end of the war with her independence and territory unimpaired, and in fact held out hopes of increase of territory at the expense of France, either in Europe or in the colonies. If the request was refused, Belgium would be treated as an enemy. An answer was required within 12 hours. This action was excused by the statement that the German Government had reliable information that French forces intended to enter Belgium. But it is now known that the whole note, including this statement, had been drafted more than a week before by the general staff. After a midnight sitting of the Belgian Council of State, presided over by the King, a refusal was handed to Herr von Below. Before this happened German troops had already crossed the frontier, and in consequence Herr von Below received his passport and was requested to leave the country immediately.

These events were decisive for Great Britain. All the doubts by which the Cabinet and large sections of the country had been assailed during the previous week were at once swept aside. On the afternoon of Aug. 3, Sir Edward Grey explained the menacing nature of the situation to the House of Commons, and on the next day (after a further statement in Parliament by the Prime Minister) an ultimatum was dispatched to Berlin requiring the German Government to respect Belgian neutrality. This was

[1] Nevertheless, it was being vigorously contended by *The Times* during this juncture that British interests and honour *were* involved, though the "pacifist" section of the London Press as vigorously denied it. (Ed. E.B.)

presented by Sir E. Goschen to Herr von Jagow; as the request was refused, he demanded his passport, and war between Great Britain and Germany began at midnight (Aug. 4–5).

BIBLIOGRAPHY.—The chief authority for the events dealt with above is the official correspondence published by the various Governments. A translation of the full text of all documents published at the beginning of the war will be found in *Collected Diplomatic Documents relating to the Outbreak of the European War*, printed by the Stationery Office (1915); there are numerous other collections, as for instance *The Times Documentary History of the War*, vols. i. and ii. (1917); Mach's *Official Diplomatic Documents relating to the Outbreak of the European War*, containing both the originals and the translations (notes unreliable; 1916); useful selections are those by Reinach, *Histoire de Douze Jours* (1917), and Max Beer, *Das Regenbogenbuch*. The original German White Book was very incomplete and has been superseded by the later publication, *Deutsche Dokumente zum Kriegsausbruch, Vollständige Sammlung der von Karl Kautsky zusammengestellten amtlichen Aktenstücke, mit einigen Ergänzungen*, edited by Graf Max Montgelas and Prof. Walter Schücking, 4 vols. (1919). There has also been published the full text of the Austrian correspondence, *Diplomatische Aktenstücke zur Vorgeschichte des Krieges 1914*, 3 parts (1919); see also Dr. Roderich Gooss, *Das Wiener Kabinett und die Entstehung des Weltkrieges* (1919). The original British White Book, on the other hand, gives a faithful and practically complete account of the action of the British Government as recorded in the official papers and correspondence in the Foreign Office Archives. To these should be added the Rumanian and the Greek White Books (*Le Livre Blanc Grec—Les Pourparlers Diplomatiques 1913–7* (1918), Berger-Levrault), also the Austro-Hungarian Red Books on the relations to Italy and Rumania.

*Other Publications.*—The very numerous works which appeared during the war are to a great extent superseded owing to the further information which is now available. Of them the more important are: J. M. Beck, *The Evidence in the Case* (1914); J. W. Headlam, *The History of Twelve Days* (1915); J. W. Headlam, *The German Chancellor and the Outbreak of War* (1915); Wm. Archer, *The Thirteen Days* (1915); C. Oman, *The Outbreak of the War, 1914–8* (1919); *J'Accuse*, by a German (Dr. Richard Grelling: 1915); Dr. Richard Grelling, *The Crime* (1917).

Of the later literature, special works and memoirs, the following are the most important: *Report of the Commission of the Paris Conference on the Responsibilities for the War*, published by Congress (*Hearings before the Committee on Foreign Relations, U.S. Senate*, 66th Congress, Treaty of Peace with Germany, 1919); *Das Deutsche Weissbuch über die Schuld am Kriege* (1919); *Zur Vorgeschichte des Weltkrieges—Beilage zu den stenographischen Berichten über die öffentlichen Verhandlungen des Untersuchungsausschusses* (1921); Karl Kautsky, *Wie der Weltkrieg entstand* (1919); for criticism see Prof. Hans Delbrück, *Kautsky und Harden* (1920); René Puaux, *Le Mensonge* (1918); E. Waxweiler, *La Belgique Neutre et Loyale* (1915); *Dr. Mühlon's Diary* (1918); Prince Lichnowsky, *My Mission to London, 1912–4* (1918); Karl Helfferich, *Die Vorgeschichte des Weltkrieges* (1919); Bethmann Hollweg, *Reflections on the World War* (1920); Jagow, *Ursachen und Ausbruch des Weltkrieges* (1919); Baron Beyens, *L'Allemagne avant la Guerre* (1915); Dr. M. Boghitschewitsch, *Kriegsursachen* (1919)—English translation, *Causes of the War* (1919, G. L. van Langenhuysen); Raymond Poincaré, *Les Origines de la Guerre* (1921); Graf Pourtalès, *Am Scheidewege zwischen Krieg und Frieden* (1919); Oberstleutnant von Eggeling, *Die Russische Mobilmachung und der Kriegsausbruch* (1919).

(J. W. H.-M.)

## EUROPE AFTER THE WAR

Under the heading of WORLD WAR, the diplomatic history of the war period itself is separately dealt with. European history was mixed up in this period with world history. It remains here to speak of the new Europe resulting from the war.

The changes produced in the political system of Europe by the war and the peace settlement were in their magnitude and importance comparable only to those embodied in the similar settlements made by the treaties of Westphalia, the Peace of Utrecht and the Congress of Vienna. The territorial settlement (see accompanying map) affected directly or indirectly every nation on the continent except Spain and Portugal. It was made partly by the treaties signed at Versailles, St. Germain, Trianon, Neuilly and Sèvres, but these left several matters undecided which have been dealt with by subsequent agreements. In the summer of 1921 the principal districts left undetermined were Upper Silesia, East Galicia, the eastern frontiers of Poland and the boundaries of Albania.

*Western Europe.*—In western Europe the most important result has been the increase in the territory and influence of France, who has recovered the lost provinces of Alsace and Lorraine, which are now again incorporated in France. Her hope was permanently to detach the left bank of the Rhine from Germany, and, by joining this territory with Belgium and Luxemburg into a French sphere of influence, to secure herself against the danger of a fresh German invasion. This object was only partially attained. By a provisional arrangement, which normally would not last more than 15 years, the principal Allied and Associated Powers, among whom in all matters of western Europe France naturally took the leading place, had the right to occupy the Rhine with the bridgeheads and virtually control all German territory on the left bank of the river; inter-Allied control was exercised by a civil commission which sat at Coblenz under French chairmanship. Clauses of the Treaty of Versailles gave the control and navigation of the Rhine to an international commission, and France had for a period of 15 years acquired certain rights over the port of Kehl on the right bank of the river. The territory of the Saar valley had also for a period of 15 years been separated from Germany and placed under the control of a commission appointed by and responsible to the League of Nations, the full ownership of the mines being given to France. The chairman of the commission was French, and French influence was dominant; French troops continued to be maintained there, a contingency not contemplated by the Treaty. The final decision as to the fate of this district was reserved for a plebiscite in 1935; under this the inhabitants would have the right to opt either for restoration to Germany, incorporation with France, or a continuance of the existing system.

The Grand Duchy of Luxemburg retained its independence and status as a sovereign State, but the close connexion with Germany was severed, and in May 1921 a treaty for economic union with Belgium was signed, under which there would be a customs union between the two countries, and the railways would be jointly managed. In addition to this, Belgium, under the Treaty of Versailles, acquired a small increase of territory at the expense of Germany in Eupen and Malmedy, and was also freed from the limitations on her full sovereignty imposed by the settlement of 1839; she henceforward took her place among the other European States without the restrictions of permanent and guaranteed neutrality. This was the end of a system which in one form or another had played an important part in European politics for some 200 years. Belgium also entered into a military convention with France.

*Central Europe.*—It was in the centre and the east of Europe that the greatest changes took place. The three great monarchies, which since the days of Catherine, Frederick the Great and Maria Theresa had dominated so large a portion of the continent, disappeared. In Petrograd, Berlin and Vienna, the old centres of authority, the court made way for Republican Government, and the great armies by which Europe was overawed ceased to exist. But the character of the change in each case was very different. Germany came out of the war a united State; all projects for disruption, for instance, in the Rhine Provinces or Bavaria, failed, and she still was in population the largest country, except Russia, on the continent of Europe, and in area second only to Russia and France. She had ceded Alsace-Lorraine to France, to Denmark the northern portion of Schleswig, to Poland the greater part of the provinces of Posen and West Prussia; the city of Danzig, which commands the mouth of the Vistula, was created a sovereign State under the guarantee of the League of Nations, but by a treaty was incorporated within the Polish customs frontier, the control of railways, port and foreign relations being given to Poland. Memel and the surrounding district were ceded to the principal Allied and Associated Powers, ultimately, no doubt, to be transferred to Lithuania. A large slice of Upper Silesia was transferred to Poland. In addition to this, for a maximum period of 15 years the left bank of the Rhine was subject to inter-Allied occupation and control, and Germany was forbidden to maintain any troops or fortifications within this area or within 50 m. of the right bank of the river, and for the same period was deprived of the Saar valley.

Even more important than the loss of territory were the economic and financial disabilities imposed on Germany by the peace settlement, and the state of internal instability caused by the Revolution. The general effect was that, for the present, Germany was unable to take any active part in European politics; she had become a passive element in the continental system and the utmost that she could do was to concentrate on the slow and arduous task of internal reconstruction, which at the best must take many years. The prime occupation of France was to secure the safeguards which would be necessary when the process of recovery had been completed.

By far the most striking of the changes was the disappearance from the map of Europe of the great Habsburg Monarchy, which since the days of Charles V. had played so important a part. This is an event to which there is no parallel in European history. It is the first time that one of the Great Powers of Europe has, not by slow and prolonged process, but by a sudden collapse, ceased to exist. As an immediate result there was added to the European system one new State (the new Austrian Republic), and three others were so changed that they might equally well be considered as new members of the family of nations.

1. The ancient kingdom of Bohemia, which since 1526 had been merged in the Habsburg possessions, reappeared under the title of Czechoslovakia. To quote the preamble to one of the treaties signed at St. Germain:—

"The union which formerly existed between the old Kingdom of Bohemia, the Margravate of Moravia and the Duchy of Silesia on the one hand, and the other territories of the former Austro-Hungarian Monarchy on the other, has definitely ceased to exist, and the peoples of Bohemia, of Moravia and of part of Silesia, as well as the peoples of Slovakia, have decided of their own free will to unite, and have in fact united, in a permanent union for the purpose of forming a single sovereign independent State under the title of the Czecho-Slovak Republic."

What this means is that to the old territories of the Bohemian Crown was added a large portion of the ancient Hungarian kingdom, which was inhabited by the Slovaks, a race closely akin to the Czechs. It was strongly urged by some that the German-speaking portions of Bohemia and Moravia should be allowed, if they so desired, to unite themselves with the new Austria or with Germany. This was wisely and inevitably refused by the Peace Conference, but, on the other hand, by a special treaty signed at Paris on July 28 1920, that portion of the small duchy of Teschen, the population of which was predominantly Polish, was separated from the rest and united with the new Poland. In addition to these territories, that portion of the kingdom of Hungary which was inhabited by the Ruthenians was also incorporated with Czechoslovakia, but the Treaty of St. Germain gave to it the right of autonomy.

2. On the south there was achieved the union in one State of nearly all the South Slavs; the small kingdom of Serbia, which a few years before the war numbered only some three million inhabitants, was increased to an important State with a pop. of 14 millions, including Croatia, part of the Banat, and portions of the former Austrian provinces of Dalmatia, Carniola and Istria. As a symbol of the changed condition, the kingdom of Serbia took the title of the Kingdom of the Serbs, Croats and Slovenes, but it is often spoken of as Yugoslavia.

3. The settlement of the frontiers between this State and the kingdom of Italy was the subject of long, arduous and often critical negotiations, which were settled finally by the Treaty of Rapallo of Nov. 1920. By this Italy acquired nearly the whole of Istria; the town of Fiume, which was the special subject of controversy, became a self-governing community, closely attached to Italy. Italy on the other hand surrendered the claims she had under the Treaty of London to other portions of the Dalmatian coast, retaining only Zara and a few islands. To the problems of Europe was added that of the Adriatic, which seems destined to become the object of rivalry between Italy, Yugoslavia and Greece. In the north, Italy acquired the most generous settlement of her claims to all Italian lands, not only Trieste and Gorizia and the Trentino, but also the whole of Tirol up to the Brenner Pass and the main chain of the Alps, and for the first time thereby extended to her natural geographical frontier; as a result of this, 700,000 German-speaking Tirolese and a large number of Slavonic race in Istria came under the Italian Crown.

4. On the east, Rumania acquired part of the Banat and the whole of Transylvania, in addition to Bessarabia, her population thereby being about doubled. Here again it was impossible to draw a line by which all the Rumanians of Hungary should be assigned to Rumania without at the same time transferring the allegiance of a large non-Rumanian population, chiefly Magyars and Czechlers (a branch of Hungarians), who also include the German colony of Siebenbürgen.

The only portion of the old monarchy which in the summer of 1921 had not been definitely assigned was the province of Galicia. It was a matter of course that the western part, purely Polish in population, should go to Poland, and in fact the incorporation was effected immediately after the conclusion of the Armistice. On the other hand East Galicia, which comprises a pop. of over 4,500,000 and an area of some 17,000 sq. m., is inhabited by a population Russian in origin and speech, to which the name of Ruthenian or Ukrainian is generally applied. The Poles, however, claimed this, partly on historical grounds and partly because of the great interests in the country of the Polish aristocracy who owned large portions of the land. No decision was arrived at by the Peace Conference, but in July 1919 the Polish army was permitted to occupy the territory; proposals for assigning it with guaranteed autonomy to Poland broke down, and the Polish Government was in 1919–21 in practically undisturbed control. In the Treaty of Sèvres of Aug. 10 1920, in which many minor frontier questions were settled, clauses were included assigning West Galicia to Poland, but the Poles refused to sign this treaty, presumably on the ground that by doing so they would appear to acquiesce in a differentiation between eastern and western Galicia; no Polish Government could afford to give up its claim to East Galicia. The result was that technically the whole of the province still belonged, in the middle of 1921, to the principal Allied and Associated Powers, to whom it was ceded by the Treaty of St. Germain on Sept. 10 1919. West Galicia must, doubtless, remain an integral part of Poland. The future of East Galicia, however, remained a source of anxiety. Poland would be satisfied with nothing less than complete and unconditional sovereignty; the British Government was morally pledged by the support which it gave to the Ruthenians during 1919 not to surrender them, without stringent safeguards, to the rule of a nation whom they professed to regard as their hereditary enemy; and a restored Russia or an independent Ukraine would probably try to establish a claim to this district.

5. Of the old Austro-Hungarian Monarchy little remained when all these cessions had taken place. On the one hand we have the ancient crown lands of the Habsburgs, Upper and Lower Austria, Salzkammergut, Tirol and Vorarlberg. The Conference having refused to permit the union with Germany which was desired by large portions of the population, these were constituted as the Republic of Austria (the title of German Austria, which was at first taken, did not receive the approval of the Paris Conference), with a pop. of about 6,000,000. It is, except for the great city of Vienna and its suburbs, a predominantly mountainous and agricultural district. The problem of the future of Austria had a dual side, that of the country and that of Vienna. No city had suffered so much by the war and the peace; cut off from former trade connexions, left with a pop. of two millions of whom so many earned their livelihood from the presence of the court and the administration, the population would have been condemned to a slow process of starvation but for the assistance provided chiefly from America and Great Britain. The future of Austria remained one of the problems of Europe. France was unalterably opposed to the union of Austria with Germany, for this would, quite apart from the serious increase to German population, produce a Germany which extended from the Alps to the Baltic, and cut off western from eastern Europe. Such a Germany would be a grave menace to the other States and would compromise both Switzerland and Czechoslovakia.

6. The proud and ancient Magyar Monarchy, which had existed for over 1,000 years, and which, by the sway it exercised over the subject Slavs and Rumans, and by the influence it wielded in the Dual Monarchy, had attained a position in Europe beyond what the numbers of the ruling race warranted, was now reduced to a small State of about seven millions. Surrounded by jealous neighbours which had grown by its fall, with frontiers equally unfavourable for defence or trade, and still suffering from the effects of the revolution, the Magyars could only watch and wait for an opportunity to retrieve something of their lost power and territory. After the Bolshevik Revolution of 1919, power came into the hands of the reactionary parties, supported by the peasants; the State was still in theory a monarchy, but a monarchy without a king. The Emperor Charles was still the crowned king of Hungary; he made two visits to the country in a vain attempt to recover his crown, but the return of a Habsburg was vetoed both by the Allies and by the other successor States, for in view of the former history and great pretensions of the House this could not be regarded as a merely domestic Hungarian matter.

The substitution of this complex of States, each with its own problems and ambitions, for the great military monarchy completely altered the whole balance of the continent. During the period immediately succeeding the Peace, they were chiefly occupied with internal matters, especially the framing of new constitutions; Czechoslovakia and Rumania were confronted with the serious problem of incorporating in the new system large numbers of unwilling citizens. The severance of old-established commercial ties necessarily caused grave dislocation of trade; all suggestions for the reëstablishment of some kind of commercial union broke down, chiefly owing to the very strong opposition to anything which might lead to the restoration of the financial and commercial supremacy of Vienna. On the other hand close relations were set up between Czechoslovakia, Rumania and Yugoslavia; these States entered into a system, to which the name of "Little Entente" was applied, which had for its first object their mutual protection against any proposal to restore the Habsburgs in Hungary, but showed also a tendency for common action even against the Western Powers.

*North-Eastern Europe.*—The Paris Conference was not in a position to determine the territorial settlement so far as it dealt with the former possessions of the Russian Empire, for the final decision on these matters required the assent of Russia, and there was at the time no recognized Russian Government and no official representative of Russia at Paris. The settlement, so far as it went, was therefore the result of local action for which the Allies had no direct responsibility. All that they could do was to insert in the Treaty of Versailles a clause that the determination of the eastern frontiers of Poland must be submitted to the principal Allied and Associated Powers.

The governing factor was the terrible fate of Russia, which far surpassed the disasters that the war had brought upon central Europe. The defeats sustained by the Russian armies had during the war brought about the occupation by German forces of Poland and of the Baltic provinces. The overthrow of the autocracy in March 1917 was followed by a complete dissolution of the Russian army; in Oct. of the same year there was established the Communist Government under Lenin and Trotsky.

By the treaties of Brest Litovsk the Bolshevik Government was forced to accept the separation from Russia not only of Poland but of the Baltic provinces and of the Ukraine, which was occupied by German forces, while at the same time the Allies supported the attempts which were being made by Kolchak and Yudenitch to overthrow the Bolsheviks. Further calamities followed. In accordance with the avowed principles of their party the first step of the new Government was to eliminate those classes—the court, the aristocracy, the bureaucracy and the middle classes—by whom hitherto the country had been administered. Large numbers, including the Tsar and Tsarina and their children, were put to death. Others fled the country, and those who remained were condemned to a life of obscurity and penury. Many doubtless succumbed to the hardships and starvation they had to endure. This action naturally brought about a state of civil war, for the representatives of the old *régime* desired to overthrow the Government which was being built up by their destruction. The condition of civil war continued for another two years. It was conducted with great ferocity on both sides, but after the failure of Denikin in South Russia in 1920 the Bolsheviks succeeded in establishing their rule over all those territories which were of Russian race and language. The long continuance of the civil war had, however, the effect for the time of preventing the Bolsheviks from a military advance towards the west, and it left the country greatly impoverished. Meanwhile, as could have been anticipated, the attempt to govern Russia in accordance with Communist doctrines failed. In particular the peasants, who were now in occupation of the land, refused to provide food for the inhabitants of the towns; the whole system of transport and production broke down, and to add to the other calamities there was a serious failure of crops both in 1920 and 1921. The Bolshevik Government was ostracized by the rest of Europe, and all attempts to extend their authority over the separated western provinces failed. After the Armistice, Poland within undefined limits was recognized by the Allies as a sovereign State, the nucleus of which was "Congress Poland"; to this were added the Polish territories taken from Germany and Austria. On the east, the new Polish State was at war with the Bolsheviks. The causes of enmity were, first, the avowed intention of the latter to impose their form of government upon Poland, and secondly the delimitation of the frontier. The Poles claimed almost the whole of the territories which had belonged to the ancient kingdom, including as they did large portions of White Russia and the Ukraine, the population of which was almost exclusively Russian. The Polish Government, however, who were also at variance with Denikin, refused to give him that assistance which might possibly have led to the success of his arms. After his collapse in the spring of 1920, the Poles, disregarding advice given them by the British Government, took the offensive, invaded the Ukraine and advanced as far as Kiev; they were unable to maintain their position; during the month of July they were rapidly driven back by the Bolshevik armies, who entered Congress Poland and nearly reached Warsaw. Negotiations for an armistice were begun at Minsk, but, owing to the excessive demands of the Bolsheviks, no agreement could be reached. Helped by French military advice and by supplies from western Europe, the Poles quickly recovered courage, and during the month of Aug., with little fighting, drove out the invading Bolshevik army and again advanced into White Russia and the Ukraine. As a result of these events negotiations were begun for an armistice, and in the early months of 1921 a series of treaties was arranged by which the whole of the western frontier of Russia was determined. This was followed by an agreement between Great Britain and Russia, by which trade relations were resumed (March 19 1921), a policy to which France was strongly opposed.

The result of these events was that there were temporarily separated from Russia all those territories included in the empire, the population of which was of non-Russian race, and five new States were added to the European system.

1. Finland had already severed herself from Russia before the end of the war, to a large extent owing to the support given to the White Government by Gen. von der Goltz and a small detachment of German troops. As soon as the war was over the Government was recognized by the Allies, and by the Treaty of Dorpat of Oct. 14 1920 the Bolsheviks also recognized the independence of the country and the boundaries were fixed. By this the connexion between Finland and Russia, which had existed since it was conquered from Sweden in 1809, ceased. Reminiscences of the older Swedish connexion were revived by a dispute which arose as to the Åland Is., which stretch across the mouth of the Gulf of Finland; the population was entirely Swedish and had expressed a desire for union with Sweden. Owing to the intervention of the Allies, this matter, which threatened to lead to war, was referred for settlement to the

League of Nations, who in May 1921 issued their award: they were to remain a part of Finland, with local autonomy.

2. The former Baltic provinces, after their separation from Russia during the war, organized themselves into three States, Latvia, Esthonia and Lithuania, with republican institutions; with the help first of the Germans and afterwards of the Allies, they succeeded after severe fighting in repelling several Bolshevik attacks, and at the beginning of 1921 Latvia and Esthonia were formally recognized by the Allies. The relations to Russia were determined by treaties signed at Reval in April 1921. Formal recognition of the Government of Lithuania by the Allies was still delayed during 1921, chiefly owing to the fact that the Poles were desirous of bringing about some kind of union between Lithuania and Poland. The boundaries of the two States remained at issue, both of them claiming the city of Vilna. After the repulse of the Bolsheviks in 1920, it was in Oct. of the same year seized by a lawless act of force on the part of the Polish Gen. Zeligowski, with the scarcely veiled connivance of the Polish Government. It was agreed that the dispute should be referred to the League of Nations.

3. The most important change was the reconstitution of an independent Poland, a natural result of the fall of the three military monarchies responsible for the partitions. The frontiers of the State created great difficulties and serious differences between the Allies, and it was only late in 1921 that, after reference to the League of Nations, a decision was arrived at regarding Upper Silesia (*see* SILESIA).

The future of this part of Europe depended on Russia and Poland. It had been the ambition of Poland, in which she was supported by France, to succeed to the position which in older days the Polish Monarchy had held, and with very extensive territory which, had all her claims been granted, would have contained a pop. of nearly 40 millions, to be a permanent barrier between Germany and Russia. But ambitions of this nature require great administrative capacity as well as extended possessions. The Poles, largely owing to the continuous warfare in which they were involved, found little time for dealing with the administrative problems; the finances fell into a state of disorder, the Polish mark being quoted in 1921 at 8,000 to the pound sterling. The amalgamation of Russian, Austrian and Prussian Poland presented grave difficulties, and there was danger lest Poland might become a source of weakness rather than of strength. The permanent peace of Europe in the east could not be secured until a friendly and pacific Government was established in Russia, and it was unlikely that any settled Russian Government would acquiesce in the complete separation of the Baltic provinces, which intervene between Russia and the sea, or in the permanent cession of large portions of White Russia and the Ukraine to Poland, inhabited as they are by a population Russian in origin and speech.

*The Balkans.*—The result of the war in the Balkans was, first, the completion of the process by which the Turkish Empire in Europe ceased to exist, and secondly a continuation of the work of the Treaty of Bucharest by which Bulgarian ambitions were sacrificed to the rival States of Serbia and Greece. By the Treaty of Sèvres the Sultan was deprived of all his European possessions except Constantinople, where he enjoyed only the shadow of authority, the Straits, so long the centre of international rivalry, being transferred to international control. The decision of the Treaty of Bucharest, by which Macedonia was divided between Serbia and Greece, was maintained; but in addition, by the Treaty of Neuilly, Greece came into the possession of the whole of the north coast of the Aegean (thereby cutting off Bulgaria from this sea) as well as Thrace, including the city of Adrianople. On the north the whole of the Dobrudja was assigned to Rumania; Bulgaria therefore came out of the war with a territory of about 71,000 sq. m. and pop. of five millions, much the smallest of the Balkan States—a great disappointment in view of the high ambitions which had been entertained such a short time before. Another new State was permanently added to Europe in Albania, which at the Assembly of 1920 was admitted as a member of the League of Nations. The final decision as to the frontiers had not yet been arrived at in 1921, owing to the difficulty of reconciling the rival ambitions of Greece and Italy. There were many other causes of unrest. The Balkan settlement had been markedly favourable to Greece, chiefly owing to the confidence given by the Allies to M. Venizelos. The Greek elections of 1920, which brought about the fall of that statesman and (after the early death of King Alexander) the restoration of Constantine, had therefore more than local importance. It seemed for the moment as though the whole basis of the settlement had been destroyed. The Treaty of Sèvres was not ratified. The Turkish National party under Kemal Pasha, which had established itself in Anatolia, with its capital at Angora, claimed for Turkey not only the whole of Asia Minor, but large parts of Thrace, including Adrianople, while the extremists went so far as to demand the restoration of the whole Turkish Empire, including Mesopotamia and Palestine. There was some evidence of serious discord between the Allies; both Italy and France entered into separate negotiations with the Kemalists. At the Conference of London, March 1921, which was attended by representatives both of the recognized Government in Constantinople and of the Kemalists, an attempt was made to find some basis of agreement between the Greeks and the Turks; this failed; a state of war followed, and though the Greeks started their campaign in Asia Minor successfully, their effort was brought to a standstill in the autumn.

Looking at Europe as a whole, it is seen that in 1921 the political system which had existed for so long, depending on the mutual rivalries and coöperation of some five or six great States, approximately equal in power, had for the time ceased to exist. Of them there remained only Great Britain, France and Italy; Germany, though she had retained her unity, was prevented from asserting her place as an independent European Power by the very stringent disarmament conditions which had been imposed upon her, and also by the economic difficulties involved in the reparation clauses of the Treaty. The immediate result therefore was the ascendancy of France, who had, at any rate for the time, regained the position as the leading continental State, which in earlier days had come to be regarded as her permanent prerogative. This position France was aiming at making permanent, first by cementing her control over all countries on the left bank of the Rhine, and secondly by the establishment of a powerful Poland, the policy of which should be subservient to that of France. The interests of Italy were concentrated on the south-east of Europe, the Mediterranean and western Asia.

As a result of the war and the peace, the immediate general control, at any rate over all matters springing out of the treaties, was vested in the "Principal Allied and Associated Powers"—Great Britain, France, Italy, the United States and Japan; as the United States did not ratify the treaties, and Japan took little part in European affairs, the group practically consisted, up to the autumn of 1921, of the three other Powers, with whom for certain purposes Belgium was associated. The organs through which they worked were the Ambassadorial Conference sitting at Paris, and the Council of Prime Ministers, which met from time to time to deal with larger political matters. It followed from this that the peace and order of the continent, which was so essential in order to give an opportunity to repair the ravages of the war and meet the grave economic difficulties under which Europe was labouring, ultimately depended upon the friendly coöperation of these three Powers. This coöperation was not maintained without difficulty. In particular there were serious differences between Great Britain and France with regard to the treatment of Germany, the execution of the reparation clauses of the Treaty, and as to Polish affairs. These reached a crisis when in March 1920 the French, without consulting their Allies, occupied Frankfurt and other towns on the right bank of the Rhine, and again in July–Aug. 1921, when there was a grave difference of opinion as to Upper Silesia. There were also open disagreements as to the Near East. The unity of aims which alone could give efficiency to their joint action was wanting.

Side by side with the Supreme Council was the League of Nations, but the relation of the two organs had not been clearly

differentiated. The League had not the power and resources to deal with matters in which larger political issues were involved, and its activities were chiefly confined to those specific matters referred to it by the treaties of peace, or to other matters of minor importance in which its help was invoked, as, for instance, the Åland Is. and Vilna. In 1921 it included all European States with the exception of Germany and Russia, but these two together represented a potential force equal to that of almost the whole of the rest of the continent, and the League was not yet able to take the position, which its advocates anticipated, of a final Court of Appeal whose decisions would be, if necessary, enforced. So far indeed the hopes of a new era in international relations had not been fulfilled. Disarmament had been imposed upon Germany, Austria, Hungary and Bulgaria, and there had been a great reduction of armaments in Holland and Scandinavia; but France and Italy maintained the older system, and the new States, intent on their independence and integrity, were determined to rely on their own strength. In particular, Poland, occupied as she had been in the war with Russia, and with the enforcement of her territorial claims on her other frontiers, maintained an army of some six or seven hundred thousand men, an army which was a heavy burden on the finances and the resources of the country.

After the Napoleonic War, the Great Alliance, supported as it was by large armies, was in fact able to impose its will upon the continent. In a not dissimilar situation France, Great Britain and Italy together had neither the resources nor the unity of will which would have been requisite even if they desired to imitate their predecessors; in particular, England, occupied with urgent difficulties of finance, and burdened with great responsibilities in other parts of the world, was intent, so far as possible, on avoiding new continental entanglements. The task of supervising the execution of the treaties of peace was in itself more than sufficient to occupy the Allies, and in consequence the smaller States were enabled to show an independence, the attainment of which was one of the avowed objects of the Allies in the war. Europe had been freed from the danger of one European predominance; it showed no disposition to accept that of the victors in the war. In this state of affairs the smaller States were tending to associate themselves in local groups—*e.g.* in Scandinavia, the Baltic States, the successor States of Austria-Hungary—and the political problems by which the continent was still distracted more and more assumed a local rather than a general character. It might be hoped that, though slowly, the animosities excited by the war would subside, and that these local groups would be able to concentrate their attention on the very urgent economic problems, the settlement of which was so essential to the future welfare of the continent.

See *A History of the Peace Conference of Paris*, edited by H. W. V. Temperley, 1920.

**EVANS, SIR ARTHUR JOHN** (1851– ), English archaeologist, was born at Nash Mills, Herts., July 8 1851, the eldest son of Sir John Evans, K.C.B. (*see* 10.2*). Educated at Harrow, Brasenose College, Oxford, and Göttingen, he was elected fellow of Brasenose and in 1884 keeper of the Ashmolean Museum at Oxford, holding this post till 1908. He travelled in Finland and Lapland in 1873–4, and in 1875 made a special study of archaeology and ethnology in the Balkan States. In 1893 he began his investigations in Crete, which have resulted in discoveries of the utmost importance concerning the early history of Greece and the eastern Mediterranean (*see* 1.246, 7.421). A member of all the chief archaeological societies in Europe, he was given hon. degrees at Oxford, Edinburgh and Dublin, and was made a fellow of the Royal Society. In 1911 he was knighted. His chief publications are: *Cretan Pictographs and Prae-Phoenician Script* (1896); *Further Discoveries of Cretan and Aegean Script* (1898); *The Mycenaean Tree and Pillar Cult* (1901); *Scripta Minoa* (1909 *et seq.*); and reports on the excavations at Knossos. He also edited, with additions, Freeman's *History of Sicily*, vol. iv.

**EVANS, SIR SAMUEL THOMAS** (1859–1918), British judge, was born at Skewen, near Neath, May 4 1859. He was educated at the local school and at London University, being afterwards admitted as a solicitor (1883). He practised for some years at Neath, but in 1891 was called to the bar, where he soon built up a large practice, his numerous Welsh connexions being of great value. In 1890 he was elected Liberal member for Mid-Glamorganshire, and held the seat until 1910. In 1901 he became a Q.C., in 1908 was elected a bencher of the Middle Temple, from 1906–8 was recorder of Swansea, and in 1908 was knighted and appointed solicitor-general by Sir Henry Campbell-Bannerman. In 1910 he was raised to the bench, becoming president of the Probate, Divorce and Admiralty division. On the outbreak of the World War the Prize court was reëstablished, and the work here done as president by Sir Samuel Evans was of the highest value, many of his judgments laying down principles of great importance. He was created G.C.B. in 1917, and died in London Sept. 13 1918.

**EVERT, ALEXEI** (1857–1917), Russian general, was born in 1857 and entered the army in 1876 after finishing his course at the infantry military school in Moscow and receiving a commission in the Volinsky Guard Regiment. He passed through the academy of the general staff, and was appointed on the general staff. Later, after commanding an infantry regiment, he was in 1900 promoted to the rank of general. In the war with Japan 1904–5, he served on the commander-in-chief's "quartermaster" (*i.e.* general) staff and later as the chief of the staff of the I. Army. In 1906 he became chief of the general staff, but very soon afterwards he was appointed commander of the XIII. Corps. In 1912 he was commander of the troops of the Irkutsk military district. In Aug. 1914, while commanding the IV. Army, he participated in the victory of the Russians in the Galician battle, for which he was awarded the cross of St. George of the 4th degree. In Oct. his army was thrown on the W. bank of the river Vistula, where under his leadership it fought in the fierce battles of the winter of 1914–5 and the summer of 1915. In Aug. 1915 he was appointed commander-in-chief of the north-western group of armies, and he extricated the armies under his charge from a very critical position during the Vilna–Molodechno operations. In 1916, in order to relieve pressure on the western front, several attempts to break through the German line were made on his front, causing great losses of men and ending unsuccessfully. In March 1917, at the beginning of the Revolution, he was relieved of his duties, and he was later reported to have been killed by the Bolsheviki.

**EXCESS PROFITS DUTY AND TAX.**—The outbreak of the World War in 1914, and the consequent gigantic increase in the public expenditure of the belligerent nations, led inevitably, not only to an increase in the weight of existing taxes, but also to a search for fresh sources from which substantial amounts of revenue could be raised. It soon became clear that, among the potential sources of additional revenue, the taxation of "excess profits" merited serious consideration, and the subject was explored in many countries, with the result that, during the war, taxes of this character were imposed in the United Kingdom, Australia, Canada, New Zealand, South Africa, France, Italy, the United States of America and other countries. The characteristic features of these taxes were:—(i.) that they were charged in respect of the profits of trading concerns as such rather than of individuals, and (ii.) that the amount payable was determined, not by reference to the total profits of a concern, but by reference to its profits in excess of a certain standard, ascertained separately in each case on a prescribed basis. It was in the basis adopted for the computation of the standard that the main difference in principle between the various taxes was found, and in this respect the taxes fell into two distinct classes. On one basis the tax may be described as essentially a tax upon war profits, inasmuch as it was levied upon profits arising during or after the war in excess of a standard representing the profits or average profits of a period prior to the war. On the other basis, the tax took the form of a tax on profits in excess of a prescribed return on capital, and the standard was generally calculated by reference to a percentage upon the capital employed in earning the profits. It was the former of these two principles which was adopted as the general basis of the tax in the United Kingdom (where a tax on excess profits was first imposed), although the latter principle

appeared as a secondary feature in the scheme. Both bases, either separately or in combination, appeared in the schemes adopted in other countries.

UNITED KINGDOM.—The taxation of excess profits in the United Kingdom was effected by means of two separate and distinct imposts, viz. the munitions exchequer payments (commonly known as the munitions levy) and the excess profits duty. The character and the causes which led to the introduction of these two imposts were essentially different. The munitions levy, which applied only to a restricted class of concerns, viz. those engaged on the production of munitions of war or work allied thereto, was not primarily designed for the purpose of raising revenue. Owing to the urgent need of producing munitions in enormous and ever-growing quantities, it became necessary in the early part of 1915 that the Government should control the operations of these concerns and lay down conditions as to the employment of labour therein, conditions which were regarded as prejudicial to labour interests, and it was ultimately arranged that, while on the one hand labour would accept the proposed conditions, the owners of such concerns would for their part agree to hand over to the Government any amount by which their profits exceeded a certain standard. The amount so handed over was the munitions levy, and this levy was thus imposed as part of what may be termed a bargain made between capital, labour and the State, in order to secure increased production of necessary war materials.

The excess profits duty, on the other hand, was imposed purely for fiscal purposes, and, unlike the munitions levy, was a tax on trades and businesses in general. But while it was essentially a means of raising large amounts of revenue, the excess profits duty met a growing popular demand for a curtailment of the large profits made in many classes of trade owing to the war. Early in the war it had become obvious that, owing to restricted supplies of, and enormously increased demands for, various commodities, huge profits were being reaped by those who traded in those commodities (*see* PROFITEERING), and there was an ever-increasing volume of opinion, which became more and more insistent as the war continued, that those huge profits, due directly to war conditions, must not be allowed to remain in the possession of private traders, but should be appropriated by the State either in whole or in part, and applied towards meeting the cost of the war. It was this growth of public feeling, the feeling that the war must not become a means whereby certain citizens could enrich themselves at the expense of the community while others were dying on the battlefield, as well as the urgent financial needs of the State, which led in the middle of 1915 to the proposals for the taxation of excess profits, and then to the actual imposition of the excess profits duty.

In the following outline the excess profits duty, although it was imposed at a later date than the munitions levy, is dealt with first, as the more important and more general.

*General Scheme of the Excess Profits Duty.*—The excess profits duty, which was first imposed by the Finance (No. 2) Act, 1915, was charged on the excess profits of businesses which were either carried on in the United Kingdom or carried on abroad and owned by persons residing in the United Kingdom. The duty extended to all classes of business, including agency, with the following exceptions, viz.: (*a*) husbandry in the United Kingdom, (*b*) offices or employments, (*c*) professions, and (*d*) commercial travellers. The duty was charged upon profits, in excess of a pre-war standard of profits, arising in an accounting period, *i.e.* a period, not exceeding 12 months in length, which normally corresponded with the period for which the accounts of the business were made up. Although the Finance (No. 2) Act, 1915, was not passed until the end of 1915, the duty was imposed with retroactive effect and charged by that Act upon the excess profits arising in any accounting period which ended after Aug. 4 1914 (the date of the commencement of the war) and before July 1 1915. The duty was regularly continued by each annual Finance Act to the year 1920 inclusive and in each case the period of charge was extended for what was practically another year. These later Acts, while introducing certain modifications of detail, did not materially affect the general scheme of the duty.

*Rate of Duty.*—The excess profits duty was originally imposed at the rate of 50%, but that rate was varied in succeeding Acts. The changes in the rate of duty at successive periods are set out in the following table.

TABLE SHOWING VARIATIONS IN THE RATE OF EXCESS PROFITS DUTY, 1915–21.

| Period of Incidence | Rate of duty on excess profit per cent. |
|---|---|
| For a year from the commencement of the first accounting period | 50 |
| From the end of the first year to Dec. 31 1916 | 60 |
| From Jan. 1 1917 to Dec. 31 1918 | 80 |
| From Jan. 1 1919 to Dec. 31 1919 | 40 |
| From Jan. 1 1920 to the termination of the duty, viz. the end of the final accounting period | 60 |

In the case of a business which commenced after Aug. 4 1914, the rate of duty was 50% in respect of any accounting period ending on or before Aug. 4 1915, and 60% for any other accounting period or part of an accounting period up to Dec. 31 1916.

*Pre-War Standard of Profits.*—As stated above, the duty was charged on profits in excess of a pre-war standard. This standard was based upon the pre-war profits of the business; but in order to avoid the imposition of too heavy a burden upon the taxpayer in cases where the pre-war profits were small in amount, alternative methods of measuring the pre-war standard were provided, the taxpayer being given the choice of adopting that standard which was most favourable to him. It must, however, be made clear that, whatever standard was adopted, it was a standard based upon actual facts and not upon hypothetical conditions. The normal standard was one based upon the average profits of the business in the best two out of the last three pre-war years. Where there had been only two years of pre-war trading, the standard was the average profits of those two years, or (at the option of the taxpayer) the profits of the second of those two years. Where there had been only one year of pre-war trading, the standard was for that year.

Alternative methods of computing the standard, which could be adopted by the taxpayer, if he so desired, were as follows:—(i.) A standard based on the average profits of four out of the last six pre-war years (restricted to cases in which the average profits of the last three pre-war years were 25% less than those of the preceding three years), and (ii.) a percentage standard, *i.e.* a standard computed at the statutory percentage rate upon the capital employed in the business. (The basis on which capital was computed and particulars of the statutory percentage rate are set out and explained in the section which follows.)

In the case of a business which had less than one year of pre-war trading or was not commenced until after the outbreak of the war, the standard was normally a percentage standard; but an alternative standard was provided, computed by reference to the pre-war earnings of the proprietor of the business, whether those earnings arose from a profession or employment or from some other business.

As regards accounting periods ended after Dec. 1919, a further alternative standard was provided (by the Finance Act, 1920) applicable in general to businesses carried on by individual owners, partnerships and private companies, whether those businesses were commenced before or after the outbreak of war. This standard, known as the substituted standard, only took effect for accounting periods ended after Dec. 31 1919. The substituted standard was computed by adding to the percentage standard a sum of £500 in respect of each proprietor working full time in the business—subject to the limitation that the standard was not to exceed £750 for each working proprietor.

*Capital and the Statutory Percentage Rates.*—The capital taken into account for purposes of excess profits duty was broadly speaking the proprietor's capital actually employed in the business, and was computed by deducting the amount of the liabilities from the value of the business assets. In making that computation the following principles were followed:—(i.) Investments outside the business were not taken into account (except in the case of investment, etc., companies), as the capital they represent was not capital employed in the business. (ii.) Debentures and other loan capital were treated as liabilities, and the amount thereof was consequently deducted in making the computation. (iii.) Assets in general (apart from cash or debts) were valued at cost (or, if not acquired by purchase, at their value when they first became assets of the business), subject to any proper deduction for wear and tear, etc. The result of a computation on these lines was an amount which, though it might differ from the amount of capital shown in the balance sheet, was a measure of the proprietor's capital, including reserves, employed in the business.

For ascertaining the percentage standard, the statutory percentage rates prescribed in the Acts relating to the excess profits duty were applied to the capital computed on the above basis.

The percentage rates, some of which were varied from time to time during the lifetime of the duty, differentiated between companies on the one hand and private businesses on the other, a lower rate being prescribed in the case of companies on the ground that in their case a deduction from profits was normally allowed in respect of remuneration paid to the directors and managers, whereas no deduction was allowed for remuneration paid to the proprietor of, or partner in, a private business.

total ordinary receipts (excluding receipts on account of public debt). Although the rates were severe, rising to 80% for 1918, the tax was collected without crippling industries owing to the high level of profits and to the protective effect of the normal exemption, the relief provisions, and the large degree of administrative discretion authorized in practically all excess-profits tax laws. Indeed, after payment of the heavy war income and profits taxes combined, the corporations of the United States had left, in each of the years 1917–9 inclusive, larger money profits than in any other year for which statistics exist, except the year 1916.

*Weakness of the Tax.*—Both political parties had promised the repeal of the excess-profits tax in the year 1921. This was partly explained by the sharp decline in its productivity under peace conditions, reflected in the statistics given above. But in the main the unpopularity of the tax was due to the effect of its high rates in stimulating extravagant expenditures by the taxpayers subject to it; the general belief (probably ill-founded in part) that it was passed on loaded with additions to the general body of consumers; its limitation to a small proportion (in number) of the business concerns; its great complexity which left the taxpayer uncertain as to his liability and threatened to cause, in the words of the Secretary of the Treasury, an administrative breakdown; and most of all to its capricious inequalities. The essential object of the tax was to lay a heavy tax upon "supernormal" income or profits. But to determine what constituted "normal" profits was a task of great difficulty. Where this normal profit was determined on the basis of pre-war profits, to use the words of the British Chancellor of the Exchequer, "prosperous concerns with a large pre-war profit standard might escape liability for the tax because their present profits, though high, are not in excess of their standard, and, at any rate, they pay tax on what all of us think an unduly low scale." In the United States, where the normal exemption was computed as a percentage of invested capital, corporations which had been liberally capitalized gained an unfair advantage over those which had been conservatively financed. The American tax unquestionably bore more heavily upon hazardous industries than upon those with more stable earnings. Thus for 1918, among corporations liable for excess-profits tax, the average ratio of the tax to net income was 30%. But construction companies paid 48%, manufacturing industries 38%, mining 25% and banks only 9%. This tax, said the Secretary of the Treasury in 1919, "encourages wasteful expenditure, puts a premium on overcapitalization and a penalty on brains, energy and enterprise, discourages new ventures, and confirms old ventures in their monopolies."

See Treasury Department, Regulation No. 41, relative to the *War Excess-Profits Tax* of 1917. (T. S. A.)

**EXCHANGES, FOREIGN** (*see* 10.50).—In no department of finance was there a greater upheaval as the result of the World War than in that of national currency-values as shown in the foreign exchanges. The theory of foreign exchange is sufficiently explained in the earlier article. It remains to deal here with the historical developments subsequent to 1910.

For some years immediately preceding the World War there had been a gradual movement on the part of all important countries towards the establishment of their currencies on a gold basis. It is true that only in England, the United States and India was there an absolutely free and unrestricted gold market, yet all the other leading countries, with the exception of China and Brazil, may be considered to have achieved this object, for although, as regards most of them, difficulties were placed in the way of those who desired to withdraw gold from their respective State banks for the purpose of export, yet it was generally understood that, in the last resource, these banks would part with gold rather than permit their exchanges to depreciate below their gold parity. The result was that exporters and importers in all these countries could trade with each other without troubling themselves about possible fluctuations in exchange. Rates moved within very narrow limits and merchants could ignore them.

Even in the case of such countries as Italy and Spain, which had not quite succeeded in stabilizing their exchanges (*i.e.* bringing their currency-values up to the gold par), the risk of loss through sudden and violent fluctuations in exchange rates was very slight. It was only when trading with China, Brazil, Portugal, and a few small South American and Central American states, that merchants felt it necessary to take exchange risks into account, and the more prudent were in the habit of avoiding such risk by buying or selling exchange for forward delivery.

Most banks and banking houses in England and elsewhere bought and sold foreign exchange, but they did not do so primarily with the object of making large profits, for very little money could be made out of exchange operations when fluctuations were small and of rare occurrence. Their chief object was to meet the requirements of their customers. Indeed, foreign banks having branches in London regarded their foreign exchange trading departments as the least expensive form of advertising. In fact, when one looks back to those times, one realizes that the currencies of nine-tenths of the world were for all practical purposes identical. One felt just as certain of getting 25 francs or 20 marks for a pound sterling as of getting twelve pence for a shilling or 100 centimes for a franc.

*War-time Conditions.*—In reviewing conditions that ruled during the early days of the war, one cannot but wonder at the remarkable adaptability of the London foreign exchange market, particularly when account is taken of the numerous obstacles and restrictions that the British Government considered necessary, for good reason, to put in the way of exchange transactions. When the British Treasury assumed complete control over the London exchange market at the outbreak of the war, they had three important objects in view: first, to prevent British capital from being sent abroad; secondly to close every avenue by which enemy nations might carry on their trade with direct or indirect assistance from England; and thirdly to enable every British or Allied trader to obtain or to dispose of all the "exchange" necessary to carry on his legitimate business.

The following are some of the difficulties that had to be contended with. All communication between England and enemy countries was strictly prohibited. All letters and telegrams to and from England were opened and read by official censors and were subject to indefinite delay, if indeed they ever reached their destination. No transactions of a "speculative" nature were permitted. No gold coin or bullion was allowed to be exported from Great Britain without a licence, which was almost always refused. Exchange dealers were not permitted to deal with neutral banks or firms unless they obtained from them their signatures to the following declaration:—

We undertake to the best of our ability that the account which you keep in our name on your books will not be utilized by us or by third parties for our account in any way which will, either directly or indirectly, assist, or be for the benefit of, any enemy of Great Britain, including any person, firm or company on any list published by His Britannic Majesty's Government and called the Statutory List; and, further, that any business whatsoever that we request you to undertake for our account will neither facilitate, nor compensate, nor clear transactions in any way or at any time connected with an enemy of Great Britain, including any person, firm or company on any list published by His Britannic Majesty's Government and called the Statutory List.

We understand this undertaking to apply to every kind of transaction for which we utilize our account with you, including (but *not* excluding any other transactions which might directly or indirectly benefit any enemy of Great Britain or her Allies as above stated):—

All sight or telegraphic payments to private individuals, firms, banks, etc., in Great Britain or other countries.

The transfer of pounds sterling and/or foreign moneys to or from neutral countries on behalf of ourselves or third parties.

The collection of remittances, coupons, drawn bonds, etc.

The opening of documentary credit for the import and/or export of goods to or from our country or other countries.

The collection and/or negotiation of cheques and bills on Great Britain and other countries.

All cheques and bills drawn by us to the order of third parties.

All payments, telegraphic and mail, that we make in sterling through your intermediary.

All moneys that you receive in sterling from other parties for the credit of our account and/or moneys ordered to be held at the disposal of third parties.

Bills domiciled payable with you.

British banks and bankers, dealing with foreign countries, had to fill up once a week and send to the Ministry of Blockade, a printed form showing under four columns:—

(a). The approximate total of available cash sterling balances held for account of persons, firms and corporations domiciled in each country (*less* overdrafts);

(b). The approximate total of British Treasury bills and other sterling bills, payable in Great Britain, *held at their free disposal* for persons, firms and corporations domiciled in each country;

(c). The approximate sterling equivalent of foreign currency balances with banks in each country;

(d). The approximate sterling equivalent of currency overdrafts "Nostro" abroad at banks in each country.

No British firm or institution was permitted to work in exchange in joint account with a neutral firm or institution. It was not permissible to execute an order for a neutral to buy or sell foreign exchange unless it was stated for whose account the order was given. It was not permissible for exchange dealers to keep in foreign countries more than the minimum cash balances necessary for keeping their accounts open. An official list was sent periodically to all exchange dealers from the finance section of the Ministry of Blockade containing the names of persons and firms whose transactions it was undesirable to facilitate or finance. The last of these lists (colloquially known as "Black Lists"), which was circulated in Dec. 1918, contained no less than 10,000 names of persons or firms with whom it was not permitted to trade either directly or indirectly. It was not permissible to telegraph in cypher, though as a concession when ordering telegraphic transfers of money one private "check" word was permitted in each telegram, but this only to lessen the risk of fraud. (A few recognized codes in general use could, however, be employed, but the telegram had to commence with the name of the code and a small fee was charged by the censor.)

Troublesome these restrictions undoubtedly were, but they were not unreasonable; and foreigners, both Allies and neutrals, recognized that they were necessary and were not intended in any way to hamper them in carrying out their own legitimate trade. A large and increasing volume of orders to buy and sell foreign exchange came to the London market from the continent of Europe and also from America, with the result that London never lost its preëminent position as the world's centre for foreign exchange. Indeed, the great increase in the volume of exchange transactions that started very shortly after the declaration of peace, when exchanges were decontrolled and all restrictions were removed, found England better equipped than ever before for maintaining its leading position.

In this connexion the three subjoined tables, A, B and C, for London business done on various foreign centres, are of interest. The first (A) shows the highest and lowest exchange quotations during a normal pre-war year, the second (B) gives similar quotations for a post-war year, and the third (C) is a record of the rates at which actual transactions took place on one day in 1921:—

TABLE A.—Pre-war Rates—1912.

| | Method of Quoting. | Lowest. | Highest. |
|---|---|---|---|
| New York. | Dollars per pound | 4·84 11/32 | 4·88 1/4 |
| Paris | Francs per pound | 25·13 | 25·29 1/4 |
| Brussels | Francs per pound | 25·31 | 25·40 |
| Germany | Marks per pound | 20·41 1/4 | 20·55 |
| Amsterdam | Guilders per pound | 12·06 1/4 | 12·10 1/2 |
| Italy | Lire per pound | 25·34 | 25·63 |
| Madrid | Pesetas per pound | 26·58 | 27·34 |
| Stockholm | Crowns per pound | 18·17 | 18·29 |
| Christiania | " " " | 18·17 | 18·29 |
| Copenhagen | " " " | 18·17 | 18·29 |
| Lisbon | Pence per milreis | 46 1/2 d. | 49 1/2 d. |
| Vienna | Crowns per pound | 24·06 1/2 | 24·25 |
| Bombay | Pence per rupee | 1s. 3 11/16 d. | 1s. 4 1/16 d. |
| Buenos Aires | Pence per gold peso | 48 1/16 d. | 48 11/16 d. |

England was by no means the only country where foreign exchange transactions were subject to strict State control. In Germany, in fact, restrictions were far greater than in England. In that country dealings in foreign exchange were confined, officially, to certain firms and banks, numbering in all 28, who were granted licences by the German chancellor permitting them to do that kind of business. The offices where such transactions were authorized were known as *Divisenstellen* or "Foreign Exchange Offices." Official rates governing exchange transactions were fixed by the State Bank. These varied from time to time. Table D (on p. 42) gives the highest and lowest official Berlin rates for the years 1916, 1917 and 1918.

It will be noticed how very steady were the Austrian, Hungarian and Bulgarian exchanges, especially during 1917. Even that on Constantinople varied only about 5% during that year. If one compares these with the variations in the French, Italian and American rates of exchanges as quoted in London in 1917, one will find that the German control was, on the whole, rather more successful, for although the difference between the highest and lowest quotations for the "pegged" dollar was barely 1/4 of 1%, that for the French franc was about 2 3/4% and that for Italy was as much as 31 per cent.

TABLE B.—Post-war Rates—1920.

| Percentage of Variation. | | Lowest. | Highest. | Method of Quoting. |
|---|---|---|---|---|
| 25·75 | Montreal | 3·65 | 4·59 | Dollars per pound |
| 25·19 | New York | 3·21 1/2 | 4·02 1/2 | " " " |
| 68·83 | Paris | 40·75 | 68·80 | Francs per pound |
| 32·90 | Holland | 8·65 | 11·50 | Guilders per pound |
| 112·00 | Italy | 50·00 | 106·00 | Lire per pound |
| 52·26 | Spain | 18·98 | 28·90 | Pesetas per pound |
| 247·82 | Portugal | 5 1/4 d. | 20d. | Pence per milreis |
| 44·21 | Norway | 18·57 | 26·78 | Crowns per pound |
| 8·44 | Sweden | 17·07 | 18·51 | " " " |
| 32·20 | Denmark | 19·60 | 25·91 | " " " |
| 205·08 | Finland | 59·00 | 180·00 | Finnish marks per pound |
| 204·16 | Germany | 120·00 | 365·00 | Marks per pound |
| 20·26 | Switzerland | 19·40 | 23·33 | Francs per pound |
| 57·55 | Belgium | 40·40 | 63·65 | " " " |
| 96·85 | Greece | 25·40 | 49·50 | Drachmas per pound |
| 170·83 | Bucharest | 120·00 | 325·00 | Lei per pound |
| 233·33 | Vienna | 480·00 | 1,600·00 | Crowns per pound |
| 246·15 | Prague | 130·00 | 450·00 | " " " |
| 521·62 | Warsaw | 370·00 | 2,300·00 | Polish mks. per pound |
| 90·77 | Rio de Janeiro | 9 1/4 d. | 18 11/16 d. | Pence per milreis |
| 44·68 | Buenos Aires | 50 1/4 d. | 73 1/4 d. | Pence per gold peso |
| 100·00 | India | 1s. 4 1/4 d. | 2s. 9 1/4 d. | Sterling per rupee |
| 29·02 | Japan | 2s. 4d. | 3s. 0 1/2 d. | Sterling per yen |
| 145·16 | Shanghai | 3s. 10 1/2 d. | 9s. 6d. | Sterling per tael |

Among the other difficulties that the German trader had to contend with were these:—No German current coins or bank-notes were permitted to be sent abroad unless permission had been obtained previously from the State Bank. No German or foreign money could be sent abroad for the purpose of acquiring securities or merchandise of any description without the permission of the State Bank. This prohibition also extended to barter. No foreign credits of any description in German currency were permissible without the sanction of the State Bank. The Imperial chancellor had the power to authorize the State Bank to requisition from the possessor any foreign currencies, foreign balances or other "means of payment abroad," giving in exchange their full value in German marks at the official exchange then ruling. Persons or institutions acquiring or disposing of foreign exchange in any shape or form were obliged to give full information as to the nature of the business in question to the State Bank, and the *Divisenstellen* were empowered to make it a condition that this information should be given before doing business with them. Persons infringing any of these regulations or found to be giving false information, rendered themselves liable to fines varying from 100 to 50,000 marks and to imprisonment for periods not exceeding one year. In addition to this, the money or goods in question might be declared forfeit to the State.

Secrecy on the part of the *Divisenstellen* was ensured by an edict rendering anyone guilty of betraying any information obtained liable to a substantial fine or imprisonment.

The business of German money changers was very much hampered and restricted by emergency legislation. Money changers were certainly permitted to buy and sell foreign currencies against their equivalent in German marks, but the total amount so exchanged for one and the same person or firm by one or more money changers on one single day could not exceed 1,000 marks, nor in one calendar month 3,000 marks, unless special permission had been granted by the State Bank. Certain exceptions were made. For instance, it was not necessary to obtain permission to send funds abroad for the purpose of providing for the necessary disbursement of ships, nor for the purchase abroad of German war bonds or exchequer bonds. That part of Belgium occupied by German troops was treated in an exceptional manner and its exchange could be purchased or sold to any extent. Still, even in Germany, a very large export and import business could be carried on with Holland, Switzerland and Scandinavia. That trade was practically impossible with more distant countries was due to the blockade and not to foreign exchange restrictions.

In order to appreciate the effect produced by the war on the mechanism of dealings in foreign exchange, it is necessary to bear in mind the position previously occupied by the sterling bill throughout the world. Owing to the fact that London had been, for a far longer period than any other country, an absolutely free market for gold, and that the Bank of England had been willing to cash its notes on presentation, in gold to any extent, both for internal use and for export, the "exchange" of the whole world centred round the sterling bill, which had come to be regarded as actual *interest-bearing gold*. Nearly every foreign state bank was in the habit of keeping a certain portion of its reserve in sterling bills, which were renewed from time to time, as they became due, and only "melted" when and as these banks desired to replenish their stocks of gold.

Another thing to be remembered is the facility with which the Government banks of England, France, Germany, Belgium, Holland and other countries, could, until the outbreak of war, control their exchanges by raising or lowering their official discount rates. If, for instance, the rate of exchange between London and Paris was such that gold was being sent in inconvenient quantities from England to France, the Bank of England would raise the bank rate (and thus the value of money) in London to a sufficient extent to make it profitable for French banks to leave their money in England, or English bankers would draw three-months bills on France, in order to meet the demand for remittances to that country. Such bills, being almost invariably of the highest quality, were eagerly sought for by French banks and readily discounted in Paris.

The *immediate* effect of the outbreak of hostilities at the opening of Aug. 1914 was to break down the whole fabric of foreign exchange throughout the world. Credit, as regards foreign exchange, for the time being ceased to exist, and in every country there was a rush on the part of bankers and merchants to bring home their credit balance from abroad and to "melt" all their foreign bills. The movement of exchanges at the beginning of Aug. 1914 was most interesting. In America, for a short time, it was quite impossible to obtain exchange to meet indebtedness by remittances to London, and the value of the pound sterling in New York in consequence rose in one day as much as 30 per cent. On the other hand, in Paris the value of the pound depreciated 4 per cent. And this was in spite of the fact that, contrary to what prevailed in other countries, no prohibition was then put on the export of gold from the Bank of England.

In London, during the Aug. 1914 bank-holiday interval, which was prolonged by Royal Proclamation from Monday the 3rd until Friday the 6th, in order to avoid a panic, one of the most important problems before the British Treasury was the re-establishment of foreign exchange, since it was recognized that, until this was accomplished, it would be quite impossible to carry on the foreign trade of the country. It was necessary in the first instance to reëstablish the position of the sterling bill. For this purpose two things were necessary:—(1) to induce English accepting houses to continue to grant legitimate trade credits, and (2) to induce banks and discount houses to discount these acceptances when created. The accepting houses realized that an unknown but probably a large proportion of their acceptances would not be provided for by the drawers at due date, while the discount houses believed that many of the bills bearing their endorsements or guaranteed by them might not be met by the acceptors. Neither acceptors nor endorsers therefore felt themselves justified in adding to their liabilities.

These two apparently insuperable difficulties were overcome by the Treasury, with the assistance of the Bank of England. The Government, by a series of proclamations, relieved the endorsers of all approved sterling bills of their liability as endorsers, and authorized the Bank of England to advance at interest to all approved English acceptors, who, for reasons connected either directly or indirectly with the war, should not receive the money necessary to meet their acceptances at maturity, loans to meet these bills, repayable on or before one year after the termination of the war. Almost immediately these measures had the desired effect, and so far as the import trade of the United Kingdom was concerned exchange very soon resumed more or less its normal position. All trustworthy export houses abroad were sure of being able to finance their exports to Great Britain, and could rely on finding a ready market in London for their sterling bills. Cash payments, owing to the irregularity of the post, were usually made by telegraphic transfers. Exchange operations resulting from British export trade were not found so easy to carry out, and it was in this connexion that the mechanism of exchange underwent most change. No belligerent country other than England had been able in the early days of the war to maintain a free discount market; and throughout Europe, in those countries where gold had hitherto been obtainable, its export was prohibited. The result was that, in continental rates of exchange on London, although there was a limit as to the extent of a fall, owing to there still being a free gold market in England, there was no limit as to a rise. As a result, no prudent bank or exchange dealer in London kept any substantial balance abroad, and portfolios of bills in foreign currency (formerly held to the value of tens of millions of pounds) were no longer maintained. Their place in the business was taken by Treasury bills.

TABLE D.—Official Rates of Exchange in Berlin.

The prohibition against selling stock-exchange securities owned by foreigners on the London market, and the difficulty in the way of selling securities held in England on any other market except that of New York, combined with the British Government having assumed practical control of all credit operations, resulted in the very early days of the war in foreign exchanges being swayed almost entirely by actual trade transactions. Thus, the American sterling exchange (London on New York) after the first month or so of the war remained at a rate then considered low, because Great Britain was importing vast quantities of food and munitions from the United States and a large adverse balance of trade was being created. On the other hand in countries like France and Italy, who made large purchases in England, the exchange rose (*i.e.* depreciated in value) to heights that had not hitherto been reached. The same thing occurred even to a greater extent with regard to the Russian exchange (rubles). Russia in pre-war days had met its large indebtedness to England to a considerable extent by the export of food-stuffs, but owing to the closing of the Black Sea and the Baltic ports it was unable to carry on its export trade to anything like the normal extent. Heavy as was the depreciation in these rates of exchange, it would have been much heavier were it not for the fact that the British Government assisted its Allies to obtain large credits in London and in other markets.

In the case of countries like Brazil, Argentina and Chili, it had become almost impossible to obtain exchange on London. This was especially the case in Brazil where the export trade is seasonal. Before the war it had been the custom for South American banks to obtain financial credits in London during the periods when trade bills were not forthcoming, and by means of bills drawn against these credits their debts to Europe were tided over. These credits were eventually liquidated by means of trade bills created during the export season. In the early stages of the war European creditors either had to wait for their money or to accept very unfavourable rates.

Nevertheless, chiefly owing to the action taken by the British Government, the mechanism of foreign exchange was less seriously affected on the whole than might reasonably have been expected. Only for a very short period and between very few countries was trade held up altogether on account of exchange difficulties, but the fluctuations of *rates* of exchange between most countries became so great that the cost of exchange soon became a very important factor and had to be reckoned with, even in transactions on which the margin of profit was considerable.

During the first year of the war the pound sterling had maintained its value fairly well in all neutral countries and particularly so in the United States, which was neutral until April 1917.

At the end of 1915 the leading exchange rates with countries open to business on the London market were as follows:—

| | | | |
|---|---|---|---|
| Montreal | 4·74¼ | Christiania | 17·25 |
| New York | 4·74¼ | Stockholm | 17·10 |
| Paris | 27·73 | Copenhagen | 17·35 |
| Amsterdam | 10·83 | Petrograd | 159 |
| Italy | 31·45 | Calcutta | 1/4⅛ |
| Madrid | 25·05 | Rio de Janeiro | 12⅛ |
| Lisbon | 34d. | Buenos Aires | 49⅛ |
| Switzerland | 24·90 | | |

England however had been pouring money into America in ever-increasing amounts, to pay not only for those commodities for the supply of which England in normal times depends to a large extent on America, such as cereals, cotton, etc.—and these at very high prices—but also for the vast quantities of war material of all kinds which were being manufactured at high pressure and even higher cost both for England and for its Allies. Exchange to meet the payments for these articles as they became due was provided partly by the export of gold. Between Oct. 1 and Dec. 31 1915, gold to the value of over seventeen million pounds sterling was withdrawn from the Bank of England for export to New York alone—partly by the proceeds of the sale through ordinary channels of the bulk of what may be described as the floating stock of American securities held in England, and partly by the calling in as they became due of all the short-term loans that had been made by English investors to America. Indeed, at the very beginning of the war, the city of New York was called upon to repay £13,500,000 that happened to fall due at that time; and as this large sum had to be found very quickly on a panicky and depleted exchange market, as high an exchange as $6.75 had to be paid per British pound for prompt cable payment. It must have been evident at the time that, owing to the fact that England had just become involved in a life and death struggle with a desperate and powerful antagonist, whereas America could not but profit through its neutrality, the pound must depreciate and the dollar appreciate. But the demand in New York had to be met regardless of cost.

It is a curious and interesting fact that when the dollar was at its worst, *i.e.* $6.75 to the pound on Aug. 3 1914, the premium on the pound in New York was $1.79, whereas when the British pound was at its lowest value, about $3.19 in Feb. 1920, it was at a discount of only $1.64½.

Very soon after the outbreak of the war, the principal foreign exchanges tended to group themselves into four divisions on the London market. These became known as the "Allied exchanges," the "Enemy exchanges," the "Neutral exchanges" and the "Eastern exchanges." Whether we take as a basis the pound sterling or the United States dollar (to which, in fact, the pound was steadily linked in value from the commencement of 1916 till four months after the Armistice was declared), we find, speaking generally, that the Allied exchanges were at a discount, the Enemy exchanges at a greater discount, and the Neutral and Eastern exchanges at a premium.

The reason is not far to seek. Of the Allies, only England and France could be described as wealthy; and—partly because the war on the western front was waged mainly on French territory so that not only the most fertile part of France but also the chief centres of French industry were devastated, and also because the French were very inadequately taxed during the whole period of the war—French international credit was not maintained on the same level as that of England. The other Allies were lacking in accumulated wealth, and very soon became financially dependent, primarily on England and to a smaller extent on France. But the leading neutrals, who in Europe comprised Holland, Spain, Switzerland and the three Scandinavian kingdoms and in S. America the Argentine Republic, were in a very favourable financial position. The European neutrals could trade to their great pecuniary advantage with both groups of belligerents, and could take full advantage of the great demand that sprang up for their produce. Spain could supply France with textiles and metals, Norway and Sweden could meet the demand for timber and paper (which was much increased by the closing of the Baltic ports), and Denmark and Switzerland were able to supply both sides with dairy produce. In addition to these advantages the important mercantile fleets of Holland, Scandinavia and Spain were able to earn large profits because of the great rise that took place in freights. Indeed, throughout the war, preference was generally given by shippers to ships owned by neutrals, because the risk of their being sunk was considered somewhat less and the rates of insurance on their cargoes were therefore materially lower.

The eastern countries, China, India and Japan, were, it is true, belligerents, but their financial burdens were but slight compared with those of their European colleagues; and since China and India were large exporters of raw materials, while Japan assumed gradually the position of Germany as the chief supplier of the less costly manufactured articles, all three countries profited greatly by the war.

It may be asked why, although the United States was a free gold market and the pound was "pegged" (see below) to the dollar, both the sterling and dollar exchanges should have been for so long a period at a considerable discount in Spain and in Scandinavia. Indeed, on one day in Nov. 1917 the pound sterling was worth no more than Kr. 9·90 in Stockholm, and in April 1918 it was only saleable at Kr. 11·90 in Christiania and Copenhagen. The explanation is that, fearing the evils that might arise from "inflation," these four countries, one after another, announced that they would no longer purchase gold in

any other form than that of their individual currencies, excepting on terms that would render such importation unprofitable. After the end of the war, when the demand for their produce slackened, these countries suffered from this somewhat original form of legislation by which gold was refused in payment. The exchanges of all of them fell to a substantial discount in New York, and three out of the four went to below their pre-war value as expressed in sterling.

*Control of Exchanges.*—Towards the end of 1915 the future outlook for sterling in New York began to assume a very serious aspect. The normal floating stock of American securities (as apart from regular investments) held in England was nearly exhausted, while the demands on America for war material were greater than ever. The British Government then decided that a supreme effort must be made to control foreign exchanges in general, and more particularly to ward off at all costs the threatened collapse in the gold (or in other words, the international) value of the pound sterling, as represented by its dollar exchange. Realizing, very wisely, that this task was too vast and too difficult to be dealt with in an adequate manner by any of the existing Government departments, they appointed a small committee which was known as the "London Exchange Committee" and gave them a free hand to deal with the situation as they thought best. The members of this Committee, which was under the chairmanship of the then governor of the Bank of England, Lord Cunliffe, included Sir Brien Cokayne (afterwards Lord Cullen), deputy-governor of the Bank of England; Sir Edward H. Holden; Sir Felix O. Schuster; Mr. Gaspard Farrer; Mr. Stanley Baldwin; the Hon. Sydney Peel. Later Mr. Baldwin retired and was replaced by Mr. H. G. Levick. The Committee were mainly men of international reputation, not only conversant with foreign exchange but also accustomed to deal with vast sums of money, and whose capacity had been proved by the success of the institutions they controlled. The activities of this Committee were not confined to American exchange, although that was considered to be its principal task, for the maintenance of the American exchange in itself was a support to the exchanges of the Allied nations and a great help to neutrals, for whose commercial transactions it was the only element of steadiness. It also watched carefully other exchanges, especially that of Holland, the wealthiest and most important of European neutral states.

Before starting their work the London Committee had to convince themselves that the means at their disposal were adequate for their task. What were these means? First came the stock of gold in the vaults of the Bank of England, over which they were given control, but this was none too large as a reserve against the Bank of England notes and the ever-increasing amount of Treasury notes that had taken the place of gold as the medium of circulation. Secondly, there was a considerable stock of gold held independently in the vaults of the London clearing banks, but this also was better left untouched if possible, as it formed a most valuable secret reserve that could be used to replenish the stock of gold held by the Bank of England should need arise, as indeed it did later on. Then there was the fresh gold coming in regularly from the gold-mines of the British Empire, averaging about £55,000,000 per annum or about 65% of the total world's production. This valuable "gold-income" was also placed at the disposal of the Committee to do with as they thought best. Finally, there was an unknown but certainly a very large quantity of foreign and colonial stocks and shares remaining in the hands of British investors and having an international market on realization: owners of these securities (*see* DOLLAR SECURITIES MOBILIZATION) were invited to sell them or to lend them to the British Government on favourable terms, and power was taken to commandeer them at market price should it become advisable to do so, but the amount forthcoming voluntarily was found to be ample.[1]

[1] The value of the foreign securities actually deposited in this way at the British Treasury reached the high figure of £438,311,000; this amount was considerably larger than had been expected. In addition to this, securities were sold to the Bank of England to the value of £46,000,000 and to the "Dollar Securities Committee"

Having completed their exhaustive enquiries, the Committee decided that the means at their disposal were adequate and that the object in view was worth the cost. They embarked on their great task in Jan. 1916, and from that date until March 1919 the pound sterling was steadily maintained at a figure in New York equivalent to about par if allowance is made for the increased cost of freight and insurance for gold. It was not until March 1919 that it was decided that, the object having been achieved, control or "pegging" might be removed and the exchange allowed gradually to take its own course without interference.

It may be mentioned here that while financial authorities have been unanimously of opinion that this "pegging" of the American and English exchanges was the greatest, the most difficult, the most far-reaching in its effects, and the most successful of all the financial schemes embarked on during the war, there are some who think that the control was enforced for a longer period than was necessary, in view of the great expense entailed and the manifest fact that an exchange cannot be stabilized by artificial means for all time.

The Anglo-American exchange was the only one that was actually "pegged" or fixed, but the other exchanges were watched with equal care, and where ordinary means did not suffice gold shipments were made to Holland as well as to America. Important negotiations were entered into with such Governments as Argentina, Uruguay, and especially Japan, and proved very useful in maintaining some sort of stability for the pound, while other understandings were effected with various banks in Scandinavia, Spain and Switzerland.

The decontrol took place without any flourish of trumpets, and it was some little time before the world realized its full significance. It was not until July 1919 that the American sterling exchange fell below $4.50, nor till Dec. of that year that it broke below the $4.00 mark. In Feb. 1920 it fell below $3.50, when it touched $3.19, the lowest point recorded. In April 1920 it temporarily rose once more to over $4.00, but subsequently declined again below that level. The fluctuations in exchange after decontrol gave rise to a vast amount of speculation.

One of the chief causes contributing to the success of the task of the London Exchange Committee was the confidence inspired in the minds of neutrals, for it stands to reason that, great as were the resources placed at their disposal, the amount of the indebtedness of England to America soon became much larger, increased as it was by England assuming responsibility of £170,044,000. The following table gives fuller details of these operations:—

| | Purchases £. | Loaned Securities £. | Total £. |
|---|---|---|---|
| Dollar bonds | 136,002,988 | 39,571,276 | 175,574,264 |
| Dollar shares | 48,263,552 | 60,718,776 | 108,982,328 |
| Sterling bonds | 27,803,232 | 115,160,124 | 142,963,356 |
| Sterling shares | 875 | — | 875 |
| Registered stocks | 4,119,358 | 171,851,047 | 175,970,405 |
| Home railways | — | 17,494,182 | 17,494,182 |
| Franc bonds | — | 338,340 | 338,340 |
| Krone bonds | — | 452,894 | 452,894 |
| Florin bonds | 9,300 | 364,550 | 373,850 |
| Florin shares | 445,091 | — | 445,091 |
| | £216,644,396 | £405,951,189 | £622,595,585 |

These figures are exclusive of a special creation of $40,000,000 Canadian Pacific Railway 4 per cent Dollar Debenture stock, deposited by the Canadian Pacific Railway Company. Of the total amount purchased, as given in the first column, *i.e.* £216,644,396, the Bank of England bought £48,600,000 and the Dollar Securities Committee £170,044,000. The deposits on loan on March 31 1919 amounted, therefore, to £405,951,000, which, with the deposits on loan sold to the Treasury, £24,360,000, and the £8,000,000 special deposit of the Canadian Pacific Railway Company, made the balance actually deposited £438,311,000. As will be seen from the above table, dollar securities constituted the major portion of those mobilized. Of the American securities, amounting to £250,543,000, which came into possession of the Treasury, £177,614,000 or more than 70 % were bought for resale in New York, and £72,928,000 or 29 % were still held in Great Britain at the time this report was made. A good deal was subsequently disposed of, bringing the total amount redeemed by the United States to about £200,000,000.

for debts contracted by its Allies for the purposes of the war. In fact, England may be said to have shouldered the entire burden until April 1917, when America joined the Allies. The neutrals believed in England's financial strength, and they also recognized that the pound sterling was interchangeable with the dollar on a basis which, with allowance for the increased cost of freight and insurance, was approximately equal to pre-war par value. In other words, since America remained on a real gold basis, and the English and American exchanges were linked together, England was for practical purposes also on a gold basis. They therefore were equally content to leave their rapidly accumulating foreign credit balances either in England or America, in whichever country a better rate of interest was obtainable. In order to offer an inducement for them to select England, the British Government authorized the Bank of England on their behalf to pay to British banks and bankers a specially high rate of interest on deposits emanating from customers in neutral states (*see* MONEY MARKET). Thus neutrals were able to get in England a rate of interest for their balances substantially higher than they could have got with equal security in America. They therefore abstained to a great extent from converting their sterling into dollars, which would have added greatly to the difficulties and expenses of the London Exchange Committee.

Vast as this operation of "pegging" the sterling exchange in America was, it was only part of a still more ambitious scheme. The object in view was to stabilize at the same time the French, the Russian and the Italian exchanges. With France success might have been possible, although France lacked one of the great essentials for that purpose, *i.e.* a gold "income." None, or practically none, of the newly mined gold of the world was controlled by France. The Bank of France, however, possessed a very large stock of gold, amounting to £169,351,920 at the beginning of 1915, and the quantity of gold coin circulating in France was larger than in England. The French also had many investments abroad even apart from their holdings of Russian securities; but they were unwilling to make the great sacrifices that were necessary to ensure success. Their taxation was infinitely lighter than that of England. The logical mind of the Frenchman argued thus:—"If we lose the war we are ruined anyway. If we win, then we shall have power to force the defeated enemy to foot our bill down to the last franc. So why worry now?" They certainly did not over-estimate the power of the conqueror to dictate his own terms, but they omitted to take into their calculations the possibility that the defeated nations might be unable to pay what was demanded of them. At any rate they endeavoured to stabilize the French franc largely on money borrowed, first from the British Government and English investors and accepting houses, and later from America. Such an attempt was foredoomed to failure, and the wonder is that they were able to keep their rate of exchange as favourable (or as far from unfavourable) as they did for so long a period. The movements of the French exchange as well as those of other countries will be seen in the annexed tables.

With Italy it was still more difficult, and the various attempts that were made to prevent a breakdown in that exchange were not very successful; but then Italy was absolutely unable to rely on its own resources, much as it might wish to have done so, and it cannot justly be accused of backwardness in the imposition of taxes. As regards Russia, the attempt might well be described as farcical, since it resulted chiefly in enabling wealthy Russians to remove their money from their own country to places of safety abroad, at the expense of the British Government and the English accepting houses, who gave their unwilling assistance not with the object of making a profit, but because their patriotism was appealed to.

Table E gives the rates of exchange on New York ruling in London at the beginning and the middle of each month from Jan. 1914 to Dec. 1920.

*Indian Exchange.*—In striking contrast to the success that crowned the efforts of the London Exchange Committee in dealing with the Anglo-American exchange, was the failure of the Indian Government to maintain the pre-war ratio between the British pound and the Indian rupee that had existed without a break since 1898.

The Anglo-Indian exchange has always been a very difficult one to deal with, and it took five years' hard work (from 1893 to 1898) on the part of a particularly well-managed department of the Indian Government to establish the ratio of 15 rupees to the English sovereign, or 1s. 4d. per rupee. With great difficulty and at vast expense to the Indian taxpayer, this ratio was maintained during the war until Aug. 1917, when the Indian Council in London announced that they would no longer sell Indian exchange under 1s. 5d. per rupee. In April 1918 the rate was raised to 1s. 6d.; in May 1919 to 1s. 8d.; in Sept. of that year to 2s. 0d.; in Nov. to 2s. 2d. and in Dec. 1919 to 2s. 4d. In Jan. 1920 the rate was reduced to 2s. 0d., at which rate it was hoped that the exchange might be maintained, but by this time the Indian Government had been forced to come to the conclusion that the task of controlling the Anglo-Indian exchange was altogether beyond their power, and having spent on their attempts well over £20,000,000 and having caused losses far exceeding this amount to the Anglo-Indian trading community, while achieving no adequate result, they abandoned the attempt to interfere with the natural movements of their exchange.

In the course of their operations they purchased from the United States practically the whole of their accumulated stock of silver, amounting to 200,000,000 ounces. They suspended their weekly offerings of rupee exchange in London, and for a considerable period offered sterling exchange on the Indian markets. But it was to no purpose. The phenomenal rise in prices of commodities up to the early days of 1920, and their subsequent rapid fall, made their task too heavy for them, and after having reached 2s. 9½d. on Feb. 14 1920, the value of the rupee fell away till it touched 1s. 3d. on March 7 1921.

It must be borne in mind, however, that it is a far simpler task to "peg" an exchange to one which remains on a free gold basis—as was that of England before the war, and as that of America still remained—than to do so to that of a country whose currency is purely a fiduciary one and is subject to violent fluctuations in countries having a gold standard. In fact, during 1920 the average gold value of the pound note was only 14s. 6d. or 27½% discount, equivalent to 4½ pence on a 1s. 4d. rupee.

*Chinese Exchange.*—From time immemorial the Chinese exchange has been based on the price of bar silver, and the rate of exchange between Shanghai and England still rises and falls with the market price in London of that metal. It is true that the fluctuations in this exchange have been extraordinarily violent in recent years, but so have the movements in the price of silver. In this connexion it may be said that a large proportion of the supplies of silver that came to the London market during 1919

and 1920 was in the form of the melted silver currencies of France, Belgium, Germany and Austria, which were withdrawn from circulation and melted into bars. So much of this silver came into that market during this period that, notwithstanding the fact that the U.S. Treasury made an agreement with the American producers to purchase an amount of silver sufficient to replace what they had sold to the Indian Government at the fixed rate of a dollar an ounce, it was obtainable in large quantities at prices considerably below what it was costing to produce it in many of the most important mines. And yet the French, Belgian, German and Austrian Governments were making substantial profits in terms of their own depreciated currencies.

*South African Exchange.*—Up to the time of the outbreak of war, there was almost a stereotyped London rate of exchange on S. Africa, never varying beyond the cost of sending gold either way—usually, buying o·5% discount, selling o·5% premium. Owing to the difficulty in getting the natives to take and circulate notes, gold was the S. African currency in common use. In normal times there is a considerable leakage of gold from S. Africa. This rose to considerable proportions after the war had commenced owing to the heavy premium on gold in other countries. Even after a law had been passed prohibiting the export of gold, a considerable amount of smuggling took place and continually reduced the amount of sovereigns held by the S. African banks. In order to replenish their stocks, the banks had to import sovereigns from England, resulting in the strange spectacle of the largest gold-producing country of the world importing gold. This was due to the fact that all the fresh gold produced by the mines was requisitioned by the British Government.

Owing to the shortage of sovereigns, and the shipping of gold being a considerable expense to the banks, exchange facilities to exporters from England were somewhat restricted, and in May 1920 a premium of 8% was charged for remittances to S. Africa. The scheme by which a Federal Reserve bank for S. Africa was authorized to issue inconvertible notes to take the place of the gold currency, caused the exchange to drop to par in Aug. 1920, and the swing of the pendulum, encouraged by a considerable increase in the import of goods, created a shortage of funds in London and sent the exchange in the other direction until 6% was charged for remittances on London in S. Africa in Nov. 1920. Hence the strange phenomenon of the currency of the greatest gold-producer in the world being at a discount as compared with the British Treasury note.

*Rates of Exchange.*—Table F gives the chief rates of exchange ruling in London on three typical days: the end of July 1914; the day on which the Armistice was declared (Nov. 11 1918); and the last working day of the year 1920. There are also given the pre-war parity rates; the highest and lowest rates touched during the war, and also the highest and lowest rates touched between Armistice day and Dec. 31 1920; and that of Aug. 10 1921. The Austrian and German rates of exchange current during the war are those obtained from neutral countries.

On Sept. 1 1921 the London rates were as follows:—New York, 3·73½; Montreal, 4·14½; Paris, 47·56; Belgium, 48·97; Italy, 84; Holland, 11·74; Spain, 28·61; Switzerland, 21·84; Stockholm, 17·16; Christiania, 27·55; Copenhagen, 21; Berlin, 319; Portugal, 6; Greece, 66½; Bucharest, 317; Finland, 258; Vienna, 3,100; Prague, 312; Warsaw, 10,650; India, 1s. 4⅛d.; Yokohama, 2s. 7½d.; Buenos Aires, 43⅛; Rio de Janeiro, 7½; Serbia, 168; Bulgaria, 450; Budapest, 1,450.

Table G shows the changes that took place in the value of the pound sterling in different countries as between pre-war basis (1914) and Dec. 31 1920, the left section showing where the pound had risen to a premium and the right section where it had fallen to a discount.

In order to understand accurately the extent of the depreciation of the various exchanges since they ceased to have a gold standard, it is better to take as a basis for comparison the American gold dollar rather than the British paper pound.

Table H shows the rates of exchange ruling in New York (*a*) immediately before the declaration of war, (*b*) just after America joined the Allies, and (*c*) when the Armistice was declared. Table I gives the rates ruling on Dec. 31 1920, and includes those of several countries not previously quoted in America.

*Speculation.*—During the war speculation in foreign exchanges was almost entirely confined to the six neutral states of Europe—Holland, Denmark, Sweden, Norway, Spain and Switzerland—and to the United States, which was free to deal in all exchanges until it came into the war in 1917. These countries traded very extensively with both groups of belligerents, and quickly amassed very large profits through selling their produce and manufactures at high prices, and also through obtaining abnormally high freights with their steamers. Much of this money was paid in the currency of the purchasing countries and large foreign balances were thereby accumulated. The natural effect was to depreciate the value of the pound, the franc, the lira, the ruble, the mark and the Austrian crown, all considerably but in different degrees. Most of the neutral export merchants and shippers became large sellers of foreign credits, and had they not been able to do so they would have been obliged to cease exporting, but there are always people in every country willing to buy almost anything at a price, and it did not take long before the speculative habit which is the invariable result of sudden prosperity was turned in the direction of foreign exchange, and not only bankers and banks but also private individuals indulged in a perfect orgy of speculation.

Many of these speculators bought sterling exchange, others bought marks. They frankly backed the side they thought would win, and gained or lost accordingly, but there were others who thought it more prudent to "hedge"—that is, to divide their risks and turn part of their money into pounds and part into marks. These persons omitted one very important factor from their calculations, *i.e.* that the prospect of loss in the value of the currency of the losing side must of necessity be immeasurably greater than the prospect of gain in that of the winning side.

TABLE I.—New York Rates, Dec. 31 1920.

| Nominal Gold Value. | | Dec. 31 1920. | Per cent of Discount. |
|---|---|---|---|
| 4·8665 dollars to £ | England | 3·52½ dollars for £ | 27·6 |
| 19·3c. to 1 franc | France | 5·89 cents for 1 franc | 69·3 |
| 23·8c. to 1 mark | Germany | 1·38 cents for 1 mark | 94·3 |
| 19·3c. to 1 lire | Italy | 3·46 cents for 1 lira | 82·1 |
| 40·2c. to 1 guilder | Holland | 31·30 cents for 1 guilder | 22·1 |
| 19·3c. to 1 peseta | Spain | 13·45 cents for 1 peseta | 30·3 |
| 19·3c. to 1 franc | Switzerland | 15·20 cents for 1 franc | 21·2 |
| 1·08 dollars to 1 escudo | Portugal | 10·30 cents for 1 escudo | 81·1 |
| 19·3c. to 1 franc | Belgium | 6·17 cents for 1 franc | 67·9 |
| 20·26c. to 1 crown | Austria | 0·24 cents for 1 crown | 98·7 |
| 20·26c. to 1 crown | Czechoslovakia | 1·15 cents for 1 crown | 94·3 |
| 19·3c. to 1 leu | Rumania | 1·28 cents for 1 leu | 93·3 |
| 19·3c. to 1 drachma | Greece | 7·35 cents for 1 drachma | 62·4 |
| 26·8c. to 1 crown | Norway | 15·65 cents for 1 crown | 41·6 |
| 26·8c. to 1 crown | Sweden | 19·85 cents for 1 crown | 26·0 |
| 26·8c. to 1 crown | Denmark | 15·65 cents for 1 crown | 41·6 |
| 19·3c. to 1 finmark | Finland | 2·90 cents for 1 finmark | 84·9 |
| 23·8c. to 1 mark | Poland | 0·17 cents for 1 mark | 99·3 |
| 51·46c. to 1 ruble | Russia | 0·45 cents for 1 ruble | 99·1 |
| 100c. to $1 | Canada | 86·6 cents for $1 | 13·4 |
| 42·45c. to 1 peso | Argentina | 38·15 cents for 1 peso | 10·1 |
| 32·44c. to 1 milreis | Brazil | 14·00 cents for 1 milreis | 56·8 |
| 48·66c. to 1 rupee | India | 26·00 cents for 1 rupee | 46·5 |
| 49·85c. to 1 yen | Japan | 48·37 cents for 1 yen | 3·0 |

For instance, a Dutch speculator might have bought £10,000 for 100,000 guilders and at the same time 300,000 marks for another 100,000 guilders: this was in the early part of 1916 when it was doubtful which side would win the war. On Jan. 1 1921, if he realized his holdings he would have gained about 10,000 guilders on his sterling but lost 70,000 guilders on his marks. Should, however, this speculator have been tempted by the greater depreciation to have bought Austrian crowns and French francs, he would have lost half his money on the realization of his francs and practically the whole when he sold his crowns. It was, however, chiefly in their mark investments that neutral states lost a large proportion of their war profits.

Another very favourite speculation was the Russian ruble. Speculation in this currency started very early in the war and continued long after the establishment of the Soviet Government. To a great extent it took the form of buying actual ruble notes, and large masses of these came to Europe partly via Scandinavia and partly through Siberia. Many of them found a home in America, but large quantities remained in Sweden and in England. It was somewhat strange that this buying of ruble notes should have continued notwithstanding frequent announcements made by the Bolshevik leaders that it was their intention to issue fresh notes in sufficient quantities to destroy effectually their value as a purchasing instrument. It was only when it was realized that the Soviet Government were printing so-called "Imperial" notes in limitless quantities, using for that purpose the original plates and producing a spurious article quite undistinguishable from the original, that the speculators at last realized that their rubles were not only absolutely worthless at the moment but that there was but slight prospect of their having any value even in the distant future.

It was not however until the Anglo-American exchange was decontrolled, and restrictions as to dealing in certain exchanges were definitely removed in the belligerent countries, that speculation became general. Decontrolled exchange without a gold basis presented all the elements dear to the speculator—an unlimited supply of the article, violent and frequent fluctuations, ease in buying or in selling to any extent, no fear of being "cornered," and an international market. The volume of speculative business soon became much larger than that of transactions done for legitimate trade purposes. But foreign trade could still be carried on without the merchant running exchange risks unless he decided to do so. A system was elaborated by which for any bona-fide trade transaction a merchant enjoying good credit could purchase or sell his foreign exchange at a rate based on that of the day on which he did his transaction, for future delivery at dates that synchronized with his requirements. It was only when trading with countries whose exchange could not be sold in the ordinary way for immediate delivery, that he was unable to arrange for his future deliveries.

*The Ter Meulen Plan.*—To avoid this difficulty, a scheme was drawn up in the autumn of 1920, known as the "Ter Meulen Scheme" (from the name of its originator, a partner in the firm of Messrs. Hope & Co. of Amsterdam). It was accepted by the League of Nations and was intended to assist impoverished nations which under existing circumstances were unable to attract funds for the financing of essential imports. Up to the end of 1921 this scheme was not in actual operation, but the plan proposed was recognized as one which would have an important bearing, if adopted, on the business of foreign exchange.

The Ter Meulen Scheme was as follows, the text of the League of Nations articles (Nov. 1920) being here slightly abbreviated:—

INTERNATIONAL CREDITS SCHEME

An International Commission shall be constituted under the auspices of the League of Nations.

The Commission shall be appointed by the Council of the League of Nations and shall have discretion to appoint agents and sub-Commissions.

The Governments of countries desiring to participate shall notify to the Commission what specific assets they are prepared to assign as security for commercial credits to be granted by the nationals of exporting countries.

The Commission, after examination of the assets, shall determine the gold value of the credits which it would approve against the security of these assets.

The participating Governments shall then be authorized to issue bonds to the gold value approved by the Commission. The bonds shall be in such form, with such date of maturity and rate of interest, as the Commission may decide and shall, in particular, enumerate the assets pledged against the bonds. The denomination of each bond and the specific currency in which it is to be issued shall be determined by the participating Government in agreement with the Commission, in accordance with the conditions applicable to the particular transactions in respect of which they are issued.

The service of these bonds which will be obligations of the issuing Government shall be specifically secured out of the revenue of the assigned assets.

The assigned assets shall be administered by the participating Government or by the International Commission as a majority of the Council of the League of Nations may determine on the proposal of the International Commission.

Out of the revenues from the assigned assets there shall be purchased foreign currencies sufficient to provide (*a*) cover for the coupons falling due in the next year, (*b*) a sinking fund calculated to redeem at maturity 10% of the bonds outstanding, (*c*) a reserve in such foreign currency or currencies as the International Commission may determine for the redemption of any bonds sold as a consequence of failure by the importer to fulfil his contract. Any surplus remaining after the provision of these services shall be at the free disposal of the participating Government.

The participating Government will be free either to pledge its own bonds as collateral for credits for approved imports on its own account or to lend the bonds to its nationals as collateral for credits for approved imports on private account.

Each bond shall before issue be countersigned by the Commission in proof of registration.

The fundamental purposes of the scheme being to facilitate and expedite the import of such raw materials and primary necessaries as will enable the borrowing countries to reëstablish production especially for export, bonds secured on the assigned assets shall not be utilized as collateral for credits for the import of other commodities.

For each borrowing country the Commission will draw up, in consultation with the participating Government, a schedule of approved imports which will be regarded as falling within the definition of raw materials and primary necessaries.

Particulars of each transaction must be registered with the Commission, which, before countersigning a registered bond will satisfy itself that the credit is for an approved import and that the period for which it is proposed to be granted is a reasonable one.

The same conditions as govern the pledge of the bonds as the collateral for credits for imports on private account shall apply in cases where the participating Government pledges its own bonds as collateral for imports on Government account.

After having received bonds duly countersigned the importer will pledge them with the exporter.

Pledged bonds shall be dealt with as follows:—(*a*) In the absence of any failure by the importer to fulfil his contract with the exporter, the coupons on their due date and the bonds as they are released shall be returned to the importer who shall return them to his Government forthwith. (*b*) In the event of the importer not fulfilling the terms of his contract, the exporter (or his assigns) may either hold the bonds until maturity, or if he prefers he may at any time sell them in accordance with the laws and customs of his country, providing that before the bonds are sold a reasonable opportunity shall be given to the issuing Government to repurchase them by paying to the exporter the amount of his claim. The proceeds of such sale shall be applied by the exporter towards covering his claims against the importer. Any surplus not required for this purpose shall be accounted for by the exporter to the participating Government. (*c*) Any coupons or bonds returned to the participating Government or purchased by such Government shall be forthwith cancelled in accordance with the regulations to be prescribed by the International Commission; cancelled bonds may subsequently with the approval of the Commission be replaced by other bonds either in the same or in a different currency in accordance with the conditions governing the original issue of bonds.

*Bank Notes.*—An unusual form of speculation sprang up during 1918–9. Orders were received in England, France and the United States from neutral countries for the purchase of English, French and American bank-notes at rates of exchange very much more favourable to the sellers than those current for ordinary bank credits. The French and the American Governments very soon forbade the export of their bank-notes but the British Government, after giving the matter mature consideration, decided that more advantages than disadvantages were to be gained by permitting the export of Bank of England notes, even if the ultimate destination of these notes were found to be the

enemy countries. It was afterwards ascertained that these bank-notes were actually bought for enemy account, and many of them are believed to have found their way to Turkey and Bulgaria. Subsequent events proved that the action of the purchasers, though perhaps not patriotic, was from a financial point of view a prudent one, as it was evident in 1918 that in the very probable event of the Allies winning the war, the value of the pound sterling in terms of their own currency was certain to increase to a far greater extent than the 10 or 15% beyond the then current rate of exchange on London that they were willing to pay to convert their currency into sterling in the only way they could do it, while at the same time circumventing the vigilance of the British Ministry of Blockade.

*Business Developments.*—One interesting and important result of the enormous increase of the volume of foreign-exchange transactions carried out in London, which, after the Armistice, established itself more firmly that ever as the world's clearing-house for that class of trade, has been a remarkable development in the business of the London foreign-exchange brokers.

Exchange brokers have existed in London for centuries, but their business was generally confined to buying and selling foreign exchange for merchants and for those bankers who had no direct relations with foreign countries. They were in the habit of meeting twice a week on the Royal Exchange, where the exchange dealers also attended, and foreign bills of exchange and cheques were then sold to the best buyers, and official rates of exchange were fixed. It is true that with the advent of the telephone it became more and more the custom to carry through the more important transactions, especially those between exchange dealers themselves, by means of telephonic communication, but such transactions were far from numerous, and, such as they were, they were generally done in a leisurely manner. Now all this is changed. The leading exchange brokers confine themselves entirely to working between the various exchange dealers. From ten in the morning until six in the evening their offices are a regular pandemonium. Some of them employ as many as 40 or 50 private telephones in addition to several general ones, and the largest of them carry through on an average about two-hundred transactions a day, mostly for very large sums. They make it their business to keep their clients posted in all the various and quick movements that occur almost from minute to minute in exchange rates, and carry out their transactions with the rapidity and accuracy without which business of that class would be impossible. They assume no financial liability, for when their contracts are passed their responsibility ceases. To succeed—and their business is a very lucrative one though their scale of commission is infinitesimal—they need discretion, integrity and intelligence. They must never discuss one client's business with another client, nor divulge the name of a buyer to a seller or vice versa, until the transaction is completed. The service the broker renders to the dealer is an extremely valuable one, and the result is that there is practically no business done between dealers without the intermediary of a broker. An interesting fact in this connexion is that, at the end of 1920, the biweekly meetings that had been held between dealers for generations "on 'Change" were abolished.

Partly because this system of employing exchange brokers enables large and numerous transactions to be carried out with great rapidity, partly because the temperament of the chief London dealers in foreign exchange is such that they are easily able to resist the temptation to speculate to any great extent on their own account, partly because those who deal in foreign exchange in London are banks and bankers of the highest standing, but more particularly because the sterling bill has by no means lost its prestige throughout the world, London has established herself more firmly than ever as the central foreign exchange market of the world, and all day and every day there is a constant flow of cables and telegrams from all quarters bringing orders to buy and sell every possible kind of exchange in amounts that were never imagined possible in pre-war days.

*Lessons of the War.*—Many lessons have been taught by the new conditions brought about by the war. One of the most important of these is that State interference with the natural movements of exchange, excepting for a limited period and with success practically assured, is a mistake and likely to lead to disastrous results. The "pegging" of the pound sterling to the American dollar—certainly so long as America was a neutral Power—proved nevertheless to be wise and legitimate. The attempts of other countries to stabilize their exchanges at that time were for the most part unsuccessful.

Another fact that has been brought to light is that, to a creditor country, especially one which depends for its prosperity to a large extent on its export trade, a favourable exchange is a distinct disadvantage, which can only be overcome if the nationals of that country are willing to invest a substantial proportion of the value of their exports in those foreign countries which buy their goods. An outstanding example of such a country is America, for up till the spring of 1921 Americans were only just beginning to acquire the habit of investing their money outside their own country; this rendered it extremely difficult for their export merchants to finance their business, as the majority of foreign importers were only able to pay for their goods by means of their own currencies.

It does not follow, however, that an American merchant would be absolutely precluded from selling goods (say) to Poland against payment in Polish marks merely because no one in America would be willing to invest his money in that country. So long as exchange dealers or speculators in another country whose own currency is in fair repute would be willing to purchase Polish marks either directly or indirectly against dollars—that is to say, either paying for the Polish marks in American dollars or in some currency that could be converted into dollars if the American exchange dealer so desired—so long could the American merchant continue to sell his goods to Poland against payment in that country's currency.

On the other hand, manufacturing countries whose exchanges have depreciated heavily and rapidly are in a very favourable position to compete in foreign markets. They can buy their raw materials abroad just as cheaply as any other country, while, as has been proved, the rise in the cost of manufacture—particularly as regards wages—lags far behind any rapid rise that may take place in exchange rates. Such a country would be able to undersell its competitors to a considerable extent while still making very large paper profits. As an example: the first serious set-back in trade that occurred in Germany after the declaration of peace, was when the German rate of exchange fell temporarily from 365 to 120 marks to the pound, in the early part of 1920. Had the internal value of the mark, that is to say its purchasing power within the boundaries of Germany, depreciated to anything approaching its external value, it would not have been possible for German trade to revive as rapidly as it did.

It is safe to predict that in a highly civilized country, well organized for trade purposes, such as Germany, the internal and external value of its currency must equalize itself approximately sooner or later, but the process is slow and gradual, and during the years that intervene it may be possible for that country to build up an export trade on so firm a basis that it would be difficult for other countries to oust it from its position, even when it is no longer helped by favourable exchange conditions. In fact, it is a mistake to suppose that any country derives advantage from the greater depreciation of another country's currency. The latter cannot afford to import from the former anything beyond its merest necessaries, and on the other hand it is able to undersell it in all competitive markets. (E. L. F.)

**EXPLOSIVES** (*see* 10.81–4).—In the World War of 1914–8 the use of high explosives went beyond anything previously known. Economic considerations played a large part in determining the types used, and their methods of manufacture. Many improvements were introduced to save labour and eliminate waste in production, but it became evident very early in the struggle that to meet the demand with existing types was a sheer impossibility, and this led to the adoption of others, hitherto untried and unproved. Apart from military uses, explosives also play an essential part in industrial work, the necessary supply

for which had also to be maintained during the war period. The main types of these had been standardized for years, but the experiences of the war have had some effect in influencing the uses of industrial explosives. The conditions which have to be met by commercial explosives are not so stringent as in the case of military explosives. Thus the latter are liable at any time to be subjected to hostile fire, and must therefore be very insensitive to shock; this precludes many of the explosives which are in use for commercial mining, etc.

*Military Uses.*—High explosives for military purposes are required for the bursting charges of artillery shells, air and trench-mortar bombs, grenades, naval mines, torpedoes, depth charges, as well as for land mines and demolitions in the field. For the two last-mentioned purposes ordinary commercial blasting explosives may on emergency be used, but a serious danger will be involved to the user if the explosive is of such sensitiveness as to be "set off" by the impact of hostile fire. On this account it is generally undesirable to use explosives containing nitroglycerine, which form such a large part of the blasting explosives produced for industrial purposes.

The choice of explosives for shells requires special care, as the shock of discharge is so great in modern ordnance that only explosives which are very insensitive to shock can be safely used. For this reason gunpowder was regarded for many years as the only safe explosive for the bursting charges of common shell. The premature explosion to which guncotton gave rise had tended to confirm this view; so that gunpowder, in spite of the comparative mildness of its explosion, remained in universal use until the introduction of picric acid by the French in 1885.

*Picric Acid.*—This was discovered by Woulffe in 1771, but its explosive properties remained for a long time unrecognized. Sprengel had demonstrated its capability of detonation in 1871. In 1885 Turpin, a French chemist, applied it to the filling of shell, for which, by reason of its stability and insensitiveness to shock, as well as its extremely violent action when properly detonated, it proved eminently suitable. Shortly after this, picric acid under various names, either with or without the addition of other substances such as collodion or paraffin wax to reduce its sensitiveness, was universally adopted by the Great Powers as a high explosive for shell-filling. Picric acid can be melted and poured into the shell, where it sets into a compact mass—the method adopted in the British service. It was first used in actual warfare by the British army in the S. African War of 1899–1902 under the name of "lyddite." Picric acid is also the main or sole constituent of the French mélinite, the Japanese shimosé powder, and the Austrian ékrasit. Lyddite can hardly be said to have fulfilled in the S. African War the somewhat exaggerated claims made for it, as the shells, especially of the smaller sizes, were uncertain in their detonation, but this was due to the fear still prevailing of premature explosion in the bore, which prevented the use of a sufficiently powerful detonating impulse in the percussion fuze being employed. In the World War of 1914–8, after this disability had been removed, through the employment of a fulminate detonator and a suitable exploder system, shells filled with lyddite were amongst the most certain and violent in their action. When completely detonated, these shells give a dense black smoke due to unconsumed particles of carbon through lack of sufficient oxygen for complete combustion. This smoke is of great assistance to the gunner in enabling him to locate their explosion and so to adjust the range as required.

The manufacture of picric acid has been carried out for many years by the so-called "pot process," and this was retained essentially unchanged throughout the war. In this process, phenol (carbolic acid) is first heated with sulphuric acid, whereby phenol-sulphonic acids are formed, as for instance in the following equation:—

$$C_6H_5OH + 2H_2SO_4 = C_6H_3(SO_3H)_2OH + 2H_2O$$

Phenol. Sulphuric acid. Phenol disulphonic acid.

This on cooling forms a buttery mass, which is then transferred to earthenware pots and diluted. Nitric acid is allowed to trickle in slowly through glass syphons, and thus converts the sulphonic acids to tri-nitro-phenol or picric acid, which has the formula $C_6H_2(NO_2)_3OH$. The residual acid is drained off and the crystals of picric acid are thoroughly washed and then carefully dried on glass plates in a warm chamber. The last operation is the most dangerous part of the manufacture and is carried out at a distance from the nitration process. The main recent developments have been directed towards increasing the yield of picric acid and economizing acids, on the one hand by recovering the residual sulphuric acid, and on the other hand by collecting the large volumes of nitrous fumes evolved during the nitration process, which were formerly allowed to go to waste, thereby causing a serious contamination of the atmosphere.

At a later stage of the war a continuous process was patented for the manufacture of picric acid. In this process the phenol sulphonic acids were caused to traverse a long trough constructed of acid-proof bricks, and nitric acid was injected through a series of aluminium jets at intervals along the trough. This method saves a great deal of handling, and is claimed to give very good yields of picric acid. Under ordinary circumstances the yield of picric acid is about 180 lb. from each 100 lb. of phenol.

An alternative process, which was introduced and used with success during the war, was based on the intermediate formation of di-nitro-phenol. This process started out from benzene and passed through the following stages:—

$C_6H_6$ Benzene. → $C_6H_5Cl$ Mono-chloro-benzene. → $C_6H_3(NO_2)_2Cl$. Di-nitro-chloro-benzene.

$C_6H_3(NO_2)_2OH$ Di-nitro-phenol. → $C_6H_2(NO_2)_3OH$. Picric acid.

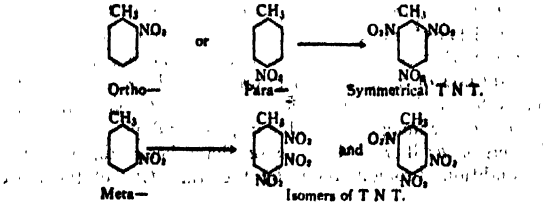
The final nitration was effected with concentrated nitric and sulphuric acids; the picric acid being washed free from acid and dried in stoves as in the phenol process.

*Trinitrotoluene* (*T N T*), which is known officially as Trotyl, is a high explosive very similar in its action to picric acid and had been discovered by Wilbrand in 1863. Its manufacture in small quantities in Great Britain had been taken up some 15 years before the outbreak of the World War, mainly for export or as ingredient of certain blasting explosives, and about 1893–4 it was made on a more considerable scale in Germany, where its value as a shell-filling became recognized some ten years later. T N T has the advantage of melting at a lower temperature than picric acid, and of not forming sensitive salts (picrates) with metals; added to which it is even less sensitive to shock and consequently less liable to give rise to premature explosions in the bore of the gun. The lower melting point of T N T (81° C.) enables it to be melted in steam-jacketed pans, whereas picric acid (121·6° C.) needs hot-air chambers or oil baths.

The manufacture of T N T in Great Britain prior to the war was very small, and the best methods had to be worked out from first principles after the outbreak of war. The existing processes were slow and wasteful, and it was necessary to find the best conditions for expediting the process and obtaining the highest possible yield of T N T with the greatest economy of sulphuric and nitric acids.

T N T is made from toluene ($CH_3C_6H_5$) by the action of nitric acid ($HNO_3$) as indicated in the following equations:—

$CH_3C_6H_5 + HNO_3 = H_2O + CH_3C_6H_4(NO_2)$ (mono-nitro-toluene)



$CH_3C_6H_4(NO_2) + HNO_3 = H_2O + CH_3C_6H_3(NO_2)_2$ (di-nitro-toluene)

$CH_3C_6H_3(NO_2)_2 + HNO_3 = H_2O + CH_3C_6H_2(NO_2)_3$ (tri-nitro-toluene).

A continuous process was introduced during the war, and proved very successful. In this process, mono-nitro-toluene entered at one end of the plant and strong sulphuric acid at the other, the nitric acid being introduced at intermediate points.

In all of these processes the product is a crude T N T of melting point 74 to 77° C. In general this is good enough for explosive purposes, but for special uses it has to be purified by crystallization or by washing with alcohol.

A more recent purification process consists of a treatment with sodium sulphite, which destroys the chief impurities—the isomeric tri-nitro-toluenes. There are six possible tri-nitro-toluenes, which differ according to the relative positions of the nitro groups in the molecule. These are all known, but only three of them are formed by direct nitration. The first stage of the nitration gives mainly ortho- and para-nitro-toluene with about 3 to 4% of meta-nitro-toluene. On further nitration, ortho- and para-nitro-toluene can give the normal symmetrical tri-nitro-toluene; the meta compound cannot do so and consequently gives other isomers as shown below:—

*Other Nitro Compounds.*—Picric acid and T N T are nitro derivatives of phenol and toluene respectively. In fact practically all military high explosives are nitro derivatives of aromatic compounds, which latter are produced from the distillation of coal tar. This source of toluene was supplemented by the use of certain natural petroleums which contain benzene and toluene, and the supplies of phenol were augmented by synthetic production from benzene, another derivative of coal tar. Nevertheless, these sources of supply were not equal to the demand, and other means of supplementing them had to be found in the war.

Thus tri-nitro-cresol, which is closely allied to picric acid, was much used by the French, as well as di-nitro-naphthalene and di-nitro-phenol, to supplement picric acid. Tri-nitro-anisol, hexa-nitro-diphenylamine, hexa-nitro-diphenyl sulphide and others were largely used by the Germans. All of these are derived from coal tar and are consequently limited to the available supply of this raw material. Only by finding some material available in larger quantity, with which these nitro compounds could be mixed, was it possible to cope with the demands. The above nitro compounds have the feature in common that they contain insufficient oxygen for their complete combustion: hence the most suitable admixture is a salt rich in oxygen.

*Ammonium Nitrate.*—Of all the available salts, the one which stands out by reason of its accessibility and suitability for the purpose is ammonium nitrate, a substance known as early as the 17th century and yet destined to play a most important part in the development of high explosives in the 20th century.

Mixtures of nitro derivatives of the aromatic compounds with ammonium nitrate, of which Roburite, Ammonal, and Dreadnought powder are amongst the best known, had long been used commercially for blasting purposes, particularly in fiery mines, where the high temperature of explosion of those containing nitro-glycerine is liable to cause explosion of the fire-damp.

Ammonium nitrate explosives are also cheap and safe both to make and to handle, owing to their great stability and insensitiveness. They are useful for many purposes where the greater *brisance* or shattering power given by nitro-glycerine is not required. One of their main disadvantages is the hygroscopicity or moisture-absorbing power of ammonium nitrate, which necessitates suitable protection or "waterproofing" from the air in order to prevent the explosive becoming so damp as to fail to respond to the detonating impulse. Although this protection can be readily given in shells and other articles of ammunition, it was probably their characteristic of deliquescence together with the difficulty of detonating such explosives effectively which was responsible for the delay in their adoption for military purposes, except possibly in Austria, where ammonal was to some extent in vogue. Moreover, the peace-time requirements before the war could be amply met in England from lyddite, of which the properties were well known. When, however, other sources of supply of high explosives in gigantic quantities had to be found, ammonium nitrate opened up the best, if not the only, solution, as far as the resources of Great Britain permitted. Yet ammonium nitrate by itself is hardly an explosive at all. By means of a very powerful detonator it is possible to cause a mild explosion and the disruption of the ammonium nitrate molecule, but under ordinary circumstances no "explosive" precautions need be taken in its manufacture or transport—a matter of considerable advantage in providing the quantities of several thousand tons a week which were required.

Prior to the World War, ammonium nitrate was made by neutralizing nitric acid with ammonia

$$HNO_3 + NH_3 = NH_4NO_3$$

Nitric acid. Ammonia. Ammonium nitrate.

but the war demands were such that it was necessary to circumvent the necessity of erecting nitric acid plants on such a large scale. This led to the introduction of methods depending on double decomposition of salts.

(1) A modification of the ammonia soda process, as indicated in the equation:—

$$NaNO_3 + NH_4{-}HCO_3 = NaHCO_3 + NH_4NO_3$$

Sodium nitrate. Ammonium bicarbonate. Sodium bicarbonate. Ammonium nitrate.

(2) From calcium nitrate, made either by the arc process or by the action of calcium chloride on sodium nitrate:—

$$2\,NaNO_3 + CaCl_2 = Ca(NO_3)_2 + 2\,NaCl.$$

Sodium nitrate. Calcium chloride. Calcium nitrate. Sodium chloride.

$$Ca(NO_3)_2 + (NH_4)_2CO_3 = CaCO_3 + 2NH_4NO_3$$

Calcium nitrate. Ammonium carbonate. Calcium carbonate. Ammonium nitrate.

(3) From sodium nitrate and ammonium sulphate:—

$$2\,NaNO_3 + (NH_4)_2SO_4 = Na_2SO_4 + 2\,NH_4NO_3$$

Sodium nitrate. Ammonium sulphate. Sodium sulphate. Ammonium nitrate.

In view of its extreme solubility in water, it is difficult to purify the ammonium nitrate completely from the salts which accompany it. The dry salt is very deliquescent and precautions must be taken after drying to avoid the introduction of moisture. A peculiarity of ammonium nitrate is that it undergoes transitions to different crystalline forms at certain temperatures, for instance at about 32° C. and 85° C. the crystalline form changes and also the specific gravity. This point is of considerable importance in shell-filling.

*Amatol.*—The high explosive which was used in the largest quantities by Great Britain during the war was "Amatol," under which name various mixtures of ammonium nitrate with T N T are comprised. These form powerful high explosives capable of detonation with a considerable velocity. "Amatol 40/60" contains 40% of ammonium nitrate to 60 of T N T and is sufficiently fluid when heated to permit of its being poured in the molten condition. "Amatol 80/20" contains 80% of ammonium nitrate, which is approximately the proportion necessary for complete combustion of the T N T. This can be compressed into shells, or forced in in a plastic condition above the melting point of the T N T. Either of these methods is much more expeditious than the operation of pouring the molten explosive into the shell and allowing it to solidify.

Apart from amatol, mention should also be made of certain other ammonium nitrate explosives which were used during the war. Ammonal had been used in Austria before the war and contained ammonium nitrate, T N T, aluminium powder, and charcoal. At a later stage the aluminium was reduced to 3%, as this metal was in great demand for air-craft purposes, and the charcoal was omitted, the resultant mixture being termed alumatol. Sabulite contained ammonium nitrate, T N T, and calcium silicide.

*War Requirements.*—The extent to which the three main high explosives were employed is well illustrated from the table on the following page of quantities manufactured in Great Britain during successive years of the war (*see also* MUNITIONS OF WAR). For the purpose of comparison, a table of industrial requirements is added, showing the amount of explosives used in mines and quarries.

So far as Great Britain was concerned, the war was practically fought on the three high explosives, picric acid (lyddite), T N T, and amatol. These necessitated enormous importations of sodium nitrate from S. America for the manufacture of nitric acid and ammonium nitrate, as well as the importation of sulphur and pyrites for the equally necessary sulphuric acid. Nitric and sulphuric acids are the life-blood of the explosives manufacture, whether it be high explosives or propellant explosives. Without the command of the sea this would have been impossible.

*Perchlorate Explosives* are analogous to the ammonium nitrate explosives. The perchlorates were discovered by Stadion in 1815. Sodium perchlorate is obtainable by electrolytic methods from common salt, and is readily converted to ammonium perchlorate. Ammonium perchlorate has the advantage of not being hygroscopic like ammonium nitrate, but on the other hand explosives made from it are generally more sensitive to shock and friction than those containing ammonium nitrate, and are consequently liable to be exploded by the penetration of a rifle bullet or the shock of discharge in a gun. An example of the ammonium perchlorate type of explosives is blastine, which was used in considerable quantities during the war. It contains ammonium perchlorate, sodium nitrate, di-nitro-toluene and paraffin wax.

*Industrial Explosives.*—Industrial explosives are not liable to be exposed to such severe conditions of mechanical shock as military explosives (shock of discharge of a shell from a gun, hostile enemy fire, etc.). This permits of the application of types

*British Military Requirements, 1914–8.*

| | 1914 from Aug. 4 | 1915 | 1916 | 1917 | 1918 | Total short tons |
|---|---|---|---|---|---|---|
| Picric acid (Lyddite), tons (2,000 lb.) | 331 | 2,475 | 18,492 | 32,053 | 15,160 | 68,511 |
| T N T, tons (2,000 lb.) | 143 | 7,347 | 51,139 | 94,796 | 84,979 | 238,404 |
| Ammonium nitrate, tons (2,000 lb.) | | 9,184 | 62,512 | 147,648 | 204,457 | 423,801 |
| *Total*, short tons | 474 | 19,006 | 132,143 | 274,497 | 304,596 | 730,716 |

*British Industrial Requirements, 1915–8.*

| | 1915 | 1916 | 1917 | 1918 | Total short tons |
|---|---|---|---|---|---|
| Gunpowder, tons (2,000 lb.) | 6,827 | 6,288 | 6,318 | 5,618 | 25,051 |
| Permitted explosives, tons (2,000 lb.) | 4,918 | 5,505 | 5,778 | 5,680 | 21,881 |
| Other explosives, tons (2,000 lb.) | 3,361 | 3,606 | 3,771 | 3,636 | 14,374 |
| *Total*, short tons | 15,106 | 15,399 | 15,867 | 14,934 | 61,306 |

of high explosives containing nitro-glycerine (dynamites, etc.), and potassium chlorate (cheddites), which are of great utility. Moreover, in industrial work great violence is not always required; in many cases it is desired to dislodge the material with as little shattering as possible, and this leads to a range of explosives differing widely in their velocities of internal combustion.

For individual classes of work special requirements have to be met; thus for blasting in enclosed spaces it is important to avoid the formation of poisonous gases such as carbon monoxide; for work in coal-mines, where inflammable dust and gases may be present, it is important to avoid explosives which give a powerful flame, and might thus ignite the coal-dust or gases.

As examples of the types of industrial explosives in use we have (1) explosives in which liquid nitro-glycerine is absorbed in wood-pulp, kieselguhr, etc., with the addition of nitrates and other salts; (2) blasting gelatine, gelatine dynamite and gilegnite, in which the nitro-glycerine is gelatinized with nitro-cotton; (3) ammonium nitrate mixtures; (4) gunpowder and various allied mixtures; (5) cheddites containing potassium chlorate mixed with castor oil and nitro compounds; (6) mixtures containing potassium and ammonium perchlorates.

In recent years the methods of liquefying air have undergone great advances, and this has led to the use of liquid oxygen for explosive purposes. A cartridge of carbonaceous material is dipped into liquid oxygen and is then inserted into the bore-hole and detonated. This forms a very direct means of supplying the oxygen necessary for the combustion of the carbon, but, as the liquid oxygen evaporates quickly, the mixture must be exploded within a few minutes, or it loses its explosive properties.

Powerful explosives may also be made by mixing liquefied nitric peroxide with combustible materials. Nitric peroxide is readily liquefied, and as its boiling point lies at 21°C., there is no difficulty in keeping it in the liquid condition. On explosion, the oxygen passes from the nitric peroxide to the combustible substances. Since, however, nitric peroxide is very poisonous, precautions must be taken in its manufacture and handling.

An interesting development in industrial explosives is their application to agricultural purposes. Useful results have been obtained, especially in America and South Africa, in breaking up hard ground and in removing tree stumps.

*Action of High Explosives.*—The destructive effect of high explosives in munitions and in the blasting of rocks is due to the very sudden pressure of gases developed, and also in the case of shells to the projection of fragments of the envelope itself.

An explosive may be defined as a substance containing potential energy which can be suddenly released through its rapid decompositions into hot gaseous products. These tend to occupy a far greater volume than the original substance from which they sprang, and in doing so exert great pressure on the containing vessel or any material with which they are in contact.

Explosives may be solids, liquids or gases, but those used for industrial or military purposes are for the most part solid, for the sake of convenience in handling, and almost invariably contain oxygen. The transformation into gas is usually due to a process of internal oxidation or burning, and the heat evolved tends further to expand the gases. Under ordinary circumstances, combustion can only take place slowly, being limited by the rate at which fresh air or oxygen can be supplied to the burning material. In explosives, on the other hand, oxygen in a loosely combined form is present in intimate contact with the combustible materials. This proximity may be merely mechanical as in the case of gunpowder, or "interatomic" as for example in T N T. Gunpowder is a purely mechanical mixture of three ingredients, potassium nitrate (saltpetre), charcoal and sulphur, each of which is in itself non-explosive. The oxygen in the potassium nitrate is striving to attach itself to the charcoal and sulphur, which form the combustible materials, and is enabled to do so as soon as external energy, usually in the form of a flame, is applied sufficient to break down the link or bond between the nitrogen or oxygen in the molecule of nitrate. Combustion can then only proceed at the points where the particles of charcoal and sulphur come into contact with the oxygen supplied to them. This explains the advantage of good incorporation and the greater rapidity of fine grain powders, but at best the proximity of the three ingredients to one another cannot be closer than is obtainable by purely mechanical means. In a high explosive such as T N T, which is a definite chemical compound ($C_6H_2(NO_2)_3CH_3$), the oxygen, loosely linked to the nitrogen, is available to unite with the carbon and hydrogen *in the same molecule*. The elements are therefore in atomic proximity and, consequently, the disruption of the molecule of T N T into hot gases can proceed at a rate which, in comparison with that of gunpowder, is almost instantaneous. The greater the volume of gases produced the greater will be the pressure formed. The rapidity with which the transformation takes place determines the disruptive effect or *brisance* of the explosion—a very high rate of explosion corresponding to a sudden blow and a low rate to a prolonged push. In high explosives the explosion wave is propagated with an acceleration until it reaches its maximum, or "velocity of detonation."

In order that the velocity may reach its maximum, it is necessary that a sufficiently powerful initiating impulse be given. In general the explosive must be confined in a metal tube in order to detonate with its maximum velocity; and since the communication of the explosion from particle to particle is retarded by many air-gaps in the mass of the explosive, some compression is usually necessary in order to enable the maximum rate of detonation, which is a definite physical constant for each explosive, to be attained.

The effect of physical condition on the mode of explosion is seen in modern smokeless propellants. Nitro-cellulose in its ungelatinized condition is a high explosive, but when gelatinized by solvents so as to form a horny compact mass (with or without nitro-glycerine) it burns relatively slowly from the exterior surface, instead of being resolved *en masse* into gas.

There is no definite line of demarcation between a "high" and what may for the want of a better term be called a "low" explosive, such as gunpowder. No intensity of initial impulse can cause the latter to explode at a greater velocity than about 300 metres per second. In the recognized high explosives the velocity of detonation may reach to about 8,000 metres per second and is never less than two or three thousand. In a slow explosive, such as gunpowder, good tamping is requisite to obtain the best results, as the gases have time to find the line of least resistance, but with a high explosive the inertia of the explosive itself and of the super-imposed atmosphere offers almost as much resistance to the intensely sudden evolution of gases as does a solid body. In consequence high explosives are sometimes said to "strike downwards." This of course is an erroneous expression, as at the moment of detonation the force of the explosion must be equal in all directions, but the tangible result of a crater blown in the ground is visible to the senses, whilst the considerably larger hole blown in the air is not. It is this untamped effect of high explosives which makes them so much more effective for most military purposes than gunpowder.

Thus we have in explosives a store of molecular energy in a condition of unstable equilibrium, requiring some form of external energy to release it. This may consist of ignition, friction, percussion or the action of a detonator, which imparts a violent shock to the explosive and at the same time emits a flash of flame.

*Mercury Fulminate.*—For stable high explosives a detonator is almost invariably used. Indeed, it is almost impossible to cause an insensitive explosive such as amatol to detonate without such an initial impulse. The discovery of fulminate of mercury by Howard about the year 1800 had a far-reaching effect on military and industrial explosives. This sensitive chemical compound is readily caused to detonate by heat, friction, or percussion.

It is consequently manufactured only under the greatest precautions in small quantities at a time. It is made by first dissolving mercury in nitric acid, and then pouring the solution into alcohol. A vigorous reaction takes place, and after a time the mercury fulminate separates out. It has then to be washed and finally dried very carefully at a low temperature.

Mercury fulminate revolutionized the methods of bringing about explosion, being first used in percussion caps for igniting gunpowder, and thereby displacing the cumbersome and uncertain method of flint and steel. At a considerably later date its value as a detonator or igniting agent for more stable high explosives became recognized, for which purpose it is now mainly used. When required simply for ignitory purposes a mixture with potassium chlorate, which causes a larger and hotter flame, is generally employed.

In order to appreciate the function of the detonator it is necessary to consider that in an explosive substance each molecule in its decomposition gives out a surplus of energy, and so provides the initial impulse required to decompose the neighbouring molecules. When, however, a high explosive such as T N T is merely ignited, the decomposition propagates itself slowly at first, and may cease altogether owing to external cooling; in any case, the velocity of decomposition increases but gradually, and it is only after a considerable quantity has decomposed that detonation ensues. As much as five tons of T N T have been known to burn off without explosive violence, though this is by no means always the case.

The particular value of fulminate of mercury as a detonating agent is due to the fact that the explosion wave is in the first place very easily initiated in it by heat or friction, and in the second place is accelerated to its maximum almost instantaneously, so that complete detonation of the bulk immediately ensues, and the detonation is similarly imparted to any high explosive, with which the fulminate is in contact. Owing to the sensitiveness of the fulminate, not more than about 10 grains of the detonating substance is employed in artillery shell. In order to communicate the detonation to the stable high explosive in a shell, it is usual to "step up" the detonation wave. Thus the fulminate detonates a core of an explosive of intermediate sensitiveness such as tetryl (tri-nitro-phenyl-methyl-nitro-amine), and this detonates the main high explosive. Similarly, when it is desired to detonate a slab of wet guncotton, it is necessary to insert a "primer" of dry guncotton between the detonator and the wet guncotton.

Detonators of standard sizes are made for commercial blasting purposes; thus the size known as No. 8, containing 30·9 grains of fulminate, is in common use for blasting, and was used during the war in Mills grenades and trench-mortar bombs, where the shock of discharge is very much less than in a gun.

Another compound which has come into use to a considerable extent as a detonating substance is lead azide ($PbN_6$). This is an example of an explosive containing no oxygen or combustible matter—its explosion is due to a simple disruption of the molecule into lead and nitrogen.

*Properties of High Explosives.*—The investigation of the behaviour of explosives on detonation is attended by considerable difficulties. Some account of recent methods is given by Sir R. Robertson in the *Journal* of the Chemical Society, 1921, vol. cxix, p. 1, from which the appended data are taken.

Important advances have been made in methods of measurement of the time-pressure curve of high explosives. The explosive is detonated at one end of a suspended steel bar and causes a wave of compression to travel along the bar. This is reflected at the far end as a wave of tension which causes a disc lightly attached to be projected into a ballistic pendulum, whereby the momentum developed over a very small time interval, usually about five millionths of a second, is obtained.

*Explosives in the Future.*—It is natural to inquire what are likely to be the future developments of explosives. If the history of the application of explosives be broadly reviewed, it is somewhat striking that the materials used for explosive purposes in the World War of 1914–8 were practically all chemical compounds which have been known for at least 50 years. Indeed, the history of the last century has been much more concerned with discoveries relating to the methods of application of explosives than the discovery of new explosive compounds. The popular imagination readily accepts stories of new explosives of fabulous violence, but experience shows that it is not in such directions that research has met with its greatest successes. Until about the middle of last century gunpowder held the field, although guncotton, nitro-glycerine, picric acid, mercury fulminate, ammonium nitrate, and the chlorates and perchlorates were all known compounds. Only one of these—namely, mercury fulminate—was used at all, and this only in its capacity as a simple igniter. The successive steps which led to the utilization of one after another of the modern explosives were first directed towards the nitric esters—nitro-glycerine and nitro-cellulose. Nitro-glycerine was brought into a form in which it could be practically used, by absorbing it into the pores of kieselguhr and later by incorporating it into gelatinized explosives, thus giving rise to extremely powerful combinations. In the utilization of nitro-cellulose, the initial problem was to bring it into a sufficiently stable condition to render it safe against spontaneous explosion. The discovery of the conversion of nitro-cellulose to a gelatinous condition by treatment with solvents led to valuable blasting explosives such as gelatine dynamite, and, more important still, formed the basis of the modern smokeless propellants.

The method of initiating the detonation of high explosives by mercury fulminate dates from 1867, and opened the way to the ultimate utilization of very insensitive explosives for blasting and military purposes. The importance of this discovery will be realized when it is considered that it rendered possible the use of a wide range of ammonium nitrate and other mixtures for industrial purposes, and the use of T N T and amatol for military purposes in the World War. Many more steps in the investigation of detonation were, however, necessary before the mechanism of gun-shells was so perfected as to give efficient detonation combined with perfect safety; and although the use of aromatic nitro compounds, as represented by picric acid, for shell purposes was introduced about 1886, it is only in the present century that the methods of detonation have been so perfected as to render these high explosives an outstanding factor in warfare.

The number of new explosives which have been patented is enormous, but these consist almost entirely of different mixtures of known ingredients, nor is it likely that any spectacular discovery will be made in the nature of a new compound of unprecedented power. In the first place, granted that the oxygen is correctly balanced against the carbon and hydrogen, the chemical energy can only be increased by lowering the heat of formation. This might be done to some extent, and compounds of somewhat

*Behaviour of Explosives on Detonation.*

| Explosive. | Total gases (c.c. per grm.) | Heat evolved (cal. per grm.) | Stability test c.c. per hr. per kilo. after 40 hrs. in a vacuum. | | | Relative insensitiveness to impact (Picric Acid = 100). | Velocity of Detonation. | |

greater power are, in fact, known, but the increase of power is almost invariably accompanied by chemical instability and mechanical sensitiveness to shock and friction, which make it difficult to apply such explosives in a practical way. Advances have been made in the discovery and application of useful intermediary explosives of the tetryl type, and there is room for further advances in this direction, but these are limited in scope. In the sphere of propellants, it appears likely that advances may be made in the direction of improvements on the present methods of gelatinizing by volatile solvents, the introduction of compounds of greater stability, and the attainment of greater power without the erosion which has hitherto limited it.

All investigations must naturally be subservient to a great extent to economic considerations. In the World War the availability of raw materials was a factor of decisive importance, and this limited the choice of compounds which could be made in large quantities. The necessity of importing the materials necessary for the manufacture of explosives is bound to direct attention to materials which can be obtained from home sources. This lends a special significance to the fixation of atmospheric nitrogen in the form of ammonia and nitric acid. It points also to the further development of perchlorates, which can be manufactured electrolytically from materials obtainable in most countries; and further investigations may overcome the present difficulties in the use of liquid oxygen.

In the future, as in the past, the advances will probably lie mainly in the direction of improvements in the methods of application of explosives, unless some method should be discovered whereby the enormous energy of disintegration of the atoms could be released at will; this cannot however be said to be within sight, and it is perhaps well that such stupendous forces should be withheld from human control until a greater sense of international responsibility is developed in mankind.

(C. D. C.; R. C. F.)

**FABRE, JEAN HENRI** (1823–1915), French entomologist, was born at St. Léons in Aveyron Dec. 21 1823. At ten years old he went to Rodez as a choir boy and there received the elements of a classical education, continuing it further at the normal school of Vaucluse. But his whole bent was for science, and, after he had become a teacher at Carpentras, he worked in his spare hours at physics and mathematics and became interested in insects, the study of whose habits was to form his life-work (*see* 3.626, 6.672, 14.180). Later he became a teacher of physics, first at Ajaccio and afterwards at Avignon. His first observations were published in *Annales des Sciences Naturelles* (1855–8), followed a good deal later by *Souvenirs Entomologiques* (1879–1907). He was a Chevalier of the Legion of Honour. He died at Serignan, Provence, Oct. 11 1915.

**FAGUET, ÉMILE** (1847–1916), French critic and man of letters (*see* 10.125*), continued up to 1914 to publish several volumes annually of critical and literary studies, more especially concerning Rousseau (*Rousseau penseur*, 1910; *Vie de Rousseau*, 1911; *Les Amies de Rousseau; Rousseau artiste*, etc., 1912). Amongst others may be noted a volume on *Madame de Sévigné* (1910); a study of *Rostand* (1911); *En lisant Molière* (1914) and *Msgr. Dupanloup* (1914). He died in Paris June 7 1916.

**FAIRBAIRN, ANDREW MARTIN** (1838–1912), British nonconformist divine (*see* 10.129), died in London Feb. 9 1912.

**FAIRBANKS, CHARLES WARREN** (1852–1918), American politician, was born near Unionville, O., May 11 1852. On graduating from Ohio Wesleyan University (1872) he became a newspaper reporter in Pittsburgh. He was admitted to the bar in 1874, and began practice at Indianapolis, Ind., where he was made solicitor for the receiver of the Indianapolis, Bloomington and Western railway. Henceforth he had much to do with railway affairs and became a railway financier. He attained a prominent place in state politics, being chairman of the Republican State Convention in 1892, 1898, and 1914. He was in charge of McKinley's campaign in Indiana, preceding the National Convention in 1896; and the following year he was elected to the U.S. Senate, having been nominated by the Republicans over several prominent candidates, including Gen. Lew Wallace. He was chairman of the U.S. representatives on the British-American Joint High Commission for dealing with Canadian questions in 1898 and 1903, being reëlected to the Senate in the latter year. At the Republican National Convention in 1904 he was unanimously nominated for Vice-President with Theodore Roosevelt and was elected. In 1912 he had a large part in the making of the Republican platform. In 1916 he was again nominated by the Republicans for Vice-President but was defeated. He died at Indianapolis June 4 1918.

**FAISAL** (1885– ), Arab Emir, third surviving son of Husein, King of the Hejaz, was born at Taif in 1885. He spent his infancy at Rihab in accordance with the tradition of the Qorcish. At the age of eight he was brought to Mecca, where he began his early studies, but was afterwards sent to Constantinople to join his father and here he received a good modern education. On attaining manhood he held official appointments under the Turkish Government. With his brothers, he took an active part in the constitutional movement which led to the deposition of 'Abdul Hamid, as a part consequence of which the emirate of Mecca was restored to his father Huseln ibn 'Ali in 1908, Faisal returning to Mecca with him. He followed a military career, and commanded the Arab contingent in the Turkish operations against the Idrisi in 1911–3. In 1914 he was elected deputy for Jidda in the Turkish Parliament. Up to that time he was not markedly prominent among his brothers, but from 1913 he favoured Arab Nationalist aspirations, and (with his brother 'Abdulla) furthered his father's anti-Ottoman designs. At the outbreak of the Arab revolt in 1916 he commanded the rebels at Medina, and, in the crisis which followed the failure to capture the city, he came much to the front. He organized the revolting tribes each under its tribal leader, devised a scheme for the formation of an Arab regular army, and developed a particular school of irregular warfare. He commanded the Arab northern forces which, after the taking of Akaba (July 1917), constituted a friendly army of the right wing of the Egyptian Expeditionary Force. He led the Arab troops at their entry into Damascus 1918, and to him, subsequently, was entrusted the task of setting up, in the eastern area of Syria, a provisional military administration to exercise control until peace was signed. Faisal presented the case of the Arabs before the Peace Conference in Paris on Feb. 6 1919. His administration maintained comparative security throughout 1919. In March 1920 he was proclaimed King of Syria at Damascus by the Syrian National Congress, but this proceeding received no official sanction from the Allied Powers, and the régime was overturned by the entry of French troops into Damascus in July of the same year, Kerak then becoming the headquarters of Faisal's administrative district. He spent some time in London in 1919 and again in 1920–21. On Aug. 23 1921—with the support of the Arab notables, ascertained by a referendum—he was crowned King of Iraq (*see* MESOPOTAMIA) and became ruler of the new State set up under the mandate accepted by the British Government.

**FALKENHAYN, ERICH VON** (1861– ), Prussian general, was born Sept. 11 1861 at Burg Belchau in the district of Thorn. He took part in the China expedition of 1900 and remained in China with a brigade of occupation till 1903. In 1906 he was appointed chief-of-staff of the XVI. and afterwards of the IV. Army Corps; in 1913 he was promoted to the rank of lieutenant-general and was appointed Prussian Minister of War. He succeeded Gen. von Moltke in Dec. 1914 as chief of the general staff of the army and was advanced to the rank of general of the infantry. It was on his initiative that the Russian lines were broken through at Gorlice–Tarnow on May 2 and 3 1915, and he likewise helped to plan the summer offensive of that year against Russia and the operations by which in the winter of 1915–6 Serbia was overrun. He was made responsible, however, for the ill-success of the German attacks of 1916 at Verdun, and was replaced as chief of the general staff by Hindenburg in August of that year. He was then assigned the leadership of the IX. Army against Rumania and commanded in the fighting at Hermannstadt and on the Targu Jin. In 1917 he took command of the so-called Asiatic Corps, for operations in the Caucasus, etc., and in 1918 and 1919 was at the head of the X. Army. He wrote an interesting account of the German conduct of the war during its first two years entitled *Die oberste Heeresleitung in ihren wichtigsten Entschliessungen 1914–16* (1919).

**FALKLAND ISLANDS BATTLE.**—The battle of the Falklands, one of the principal naval actions of the World War, was fought on Dec. 8 1914 to the S.E. of the Falkland Is., between a British battle-cruiser squadron under Vice-Adml. Sir F. Doveton Sturdee and the German East Asiatic Squadron under Adml. Graf von Spee. The British ships were:—

"Invincible," (flag.), Capt. Percy Beamish, b. c., 1908, 8 12-in., 25½ knots.
"Inflexible," Capt. R. F. Phillemore, b. c., 1908, 8 12-in., 25½ knots.
"Carnarvon" (Rear-Adml. A. P. Stoddart), Capt. H. L. Skipwith, a. c., 1904, 4 7·5-in., 6 6-in., 20 knots.
"Cornwall," Capt. W. M. Ellerton, a. c., 1904, 14 6-in., 22½ knots.
"Kent," Capt. J. D. Allen, a. c., 1903, 14 6-in., 22 knots.
"Glasgow," Capt. John Luce, l. c., 1910, 2 6-in., 10 4-in., 25½ knots.
"Bristol," Capt. B. H. Fanshawe, 1911, 2 6-in., 10 4-in., 25½ knots.
"Macedonia," Capt. B. S. Evans, a. m. s.

The following composed the German squadron:—

"Scharnhorst," a. c., 1907, 8 8·2-in., 8 5·9-in., 22½ knots.
"Gneisenau," a. c., 1908, 8 8·2-in., 6 5·9-in., 22½ knots.
"Leipzig," l. c., 1906, 10 4·1-in., 22½ knots.
"Nürnberg," l. c., 1908, 10 4·1-in., 23 knots.
"Dresden," l. c., 1908, 10 4·1-in., 25½ knots.
Also three supply ships, "Seydlitz," "Baden," "Belgrad."

** These figures indicate the volume and page number of the previous article.*

Admi. Sturdee had arrived at Stanley Harbour, in the Falklands, only the day before, in the forenoon of Monday, Dec. 7. The " Canopus," an old battleship, was already there, moored in Port Stanley waiting in conjunction with a body of sturdy volunteers to resist von Spee's expected attack. It was Admi. Sturdee's intention to coal at once and continue the pursuit of von Spee on the 9th, but his own colliers had not arrived and there were only three in harbour. It was arranged that the " Carnarvon," " Bristol " and " Glasgow " should coal first, the battle cruisers next, and the " Kent " and " Cornwall " last. The squadron was ordered to keep steam for 12 knots at two hours' notice, and the " Macedonia," an armed merchant ship,

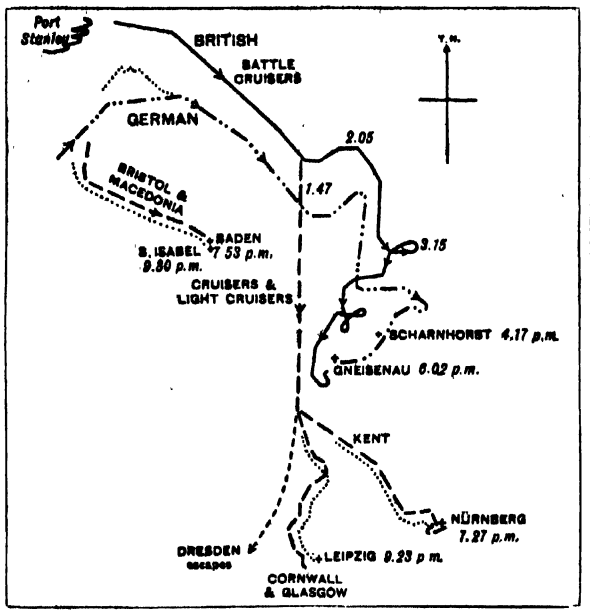

FIG. 1.—Battle of Falklands.

took the guard for the night. No sooner had coaling started than it was found that the coal in one collier had deteriorated, and at first only two colliers were available. The " Carnarvon " and " Glasgow " had finished by 6 A.M., and at first flush of dawn the " Bristol " and " Invincible " started to coal. By this time another collier had arrived, and the " Inflexible " began coaling about the same time. The " Kent," " Bristol " and " Cornwall " had not begun. The " Bristol " had her fires drawn to remedy defects, and the " Cornwall " an engine opened up at six hours' notice. This was the situation when, at eight o'clock, the " Glasgow " fired a gun. This was to call attention to a signal which had been flying for some minutes at the look-out station on Sapper Hill. It reported two strange ships in sight. A scene of bustle and commotion ensued. Colliers were cast off and great clouds of smoke began to pour from the funnels as the ships raised steam. At 8:14 A.M. the signal went up to prepare to weigh. The " Kent " by this time had taken over guard from the " Macedonia " and had passed down the harbour towards the entrance. The ships which had appeared so unexpectedly on the scene were the " Gneisenau " and " Nürnberg," which von Spee had sent on in advance. They approached from the south-west to within about 14,500 yd. and the men could be seen fallen-in on their decks ready to effect a landing. They were not in sight from the " Canopus," but a fire control station had been set up on the hill, and at 9 A.M. she opened fire with her 12-in. guns over the sand dunes. The shots fell short, but they made the " Gneisenau " turn away for a time to increase the range. The " Scharnhorst " was still some 15 m. from the entrance, but the clouds of smoke rising over the hills had aroused von Spee's suspicions and he ordered the supply ships to keep away. From the " Gneisenau " there came a report of six men-of-war in the harbour, and the Admiral ordered steam in all boilers, directing the " Gneisenau " at the same time to steer east and not to accept battle. By 10 A.M. the " Invincible," " Inflexible " and " Cornwall," which by dint of strenuous exertions on the part of her engine-room staff had got steam up, were under weigh and leaving harbour. They were vomiting out huge clouds of smoke which concealed them for a time, but it cleared away for a few minutes, revealing the tripod masts of battle cruisers, and von Spee knew that his hour of trial had come.

By 10:20 Sturdee was clear of the harbour; the enemy was well down to the south-east about 11 m. off and the British Admiral hoisted the " General Chase," a signal for each ship to steam as hard as she could after the enemy. It was a perfect summer day with a blue cloudless sky and calm sea. A light wind was blowing from the north-west. Masses of black smoke were pouring from the battle cruisers' funnels and a great white wake was growing at their stern.

The engagement resolves itself into two phases. A chase from 10:20 A.M. to 1:28 P.M. and the action from 1:28 P.M. to 6:10 P.M. (*see* figs. 1 and 2). By 11 A.M. the enemy were showing above the horizon and the battle cruisers had eased to 24 knots. The " Glasgow " was on the " Invincible " port bow, the " Kent " on her quarter. The " Carnarvon " and " Cornwall " were five m. astern, and to give Rear-Admi. Stoddart in the former a chance to get up the Admiral reduced to 20 knots. The " Bristol " by extraordinary exertions on the part of her engine-room staff had managed to raise steam. Some ladies off Port Darwin

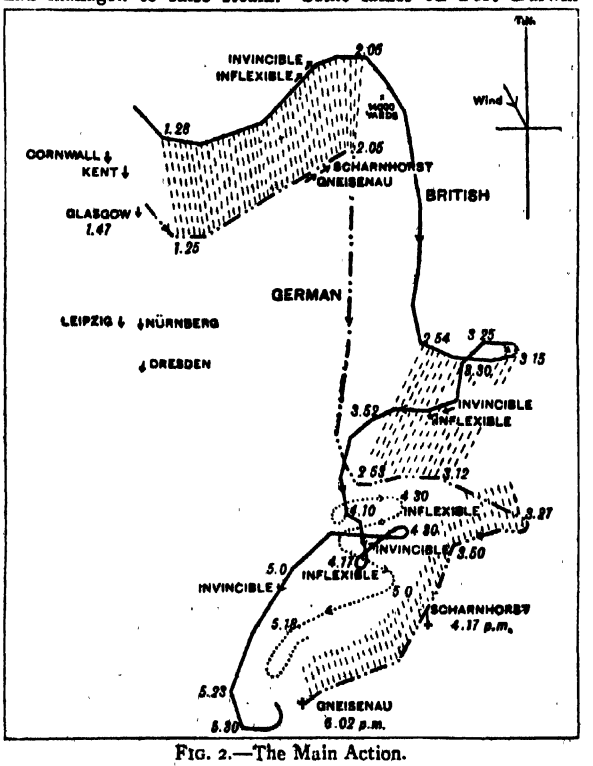

FIG. 2.—The Main Action.

had seen von Spee's colliers, and the information was passed to Port Stanley and then to Admi. Sturdee, who dispatched the " Bristol " and " Macedonia " to deal with them. By 11:30 A.M. the chase was gradually coming round to south-east by east. The " Carnarvon's " efforts to get up were unavailing and Sturdee increased speed. By 12:50 P.M. the battle cruisers were going 25 knots, overhauling the enemy fast.

The " Leipzig " was beginning to feel the pace and was dropping behind. At 12:55 P.M. her range had dropped to 16,000 yd. and the " Inflexible " opened fire. Von Spee seeing his light cruisers in danger ordered them to scatter, and they broke off to the southward, but Admi. Sturdee was ready for the con-

tingency, and the "Glasgow," "Cornwall" and "Kent" went after them in hot pursuit. Von Spee turned to E.N.E. to accept action and took station ahead of the "Gneisenau," while Sturdee's battle cruisers to the northward of him turned into line ahead on an easterly course. At 1:25 P.M. they opened fire, the "Invincible" on the "Gneisenau" and the "Inflexible" on the "Scharnhorst," at first, shifting target later when the "Scharnhorst" passed ahead.

The action which followed may be divided into three phases; an opening encounter from 1:25 P.M. to 2 P.M., then a pause from 2 P.M. to 2:45 P.M. in which the chase was resumed, and the final engagement. The opening shots were fired at about 14,000 yd., and von Spee led round to the north-east for a few minutes to close, continuing at 13,000 yd. on a north-easterly course, which gave the "Carnarvon" a chance of coming up. About 1:40 P.M. the "Invincible" was hit, and Sturdee turned to port to open the range and take advantage of his heavier guns.

Dense clouds of smoke were pouring from the battle-cruisers' funnels, and the north-easterly course and north-westerly wind carried it southward towards the enemy, smothering the range. By 2 P.M. the range had increased to 16,000 yd. and fire was checked. The "Invincible" led round to the south-east at 2:05 P.M. to close, but the enemy was lost to sight for a few minutes in the smoke, and when he reappeared he was found to have turned right away to the southward in the direction of his light cruisers. Sturdee in reply turned to the southward and increased speed, and the chase began again. It continued for nearly 40 minutes. By 2:45 the range was down again to 15,000 yd. and turning two points to port Sturdee opened fire. Von Spee did not reply for some minutes, then deciding to accept action he turned to the east again and opened fire at 2:55 P.M. The action ran to the eastward till 3:15 P.M. with the range falling from 12,000 to 10,000 yards.

The British guns were now establishing their mastery. A fire had broken out in the "Scharnhorst" and the "Gneisenau" was listing and showing signs of severe damage. But again the smother of smoke down the range made spotting difficult, and at 3:15 P.M. Adml. Sturdee to escape from it turned the battle cruisers to port together. The "Inflexible" was now leading to the westward and found herself for the first time free from smoke. Von Spee might have continued his course to the eastward which would have opened the range again to something like 17,000 yd. at the expense of a concentration of fire on the "Gneisenau" in rear, but he preferred to continue the battle on a parallel course, and led round to starboard in succession bringing his starboard guns into action. The "Scharnhorst" shifted fire to the "Inflexible" and was engaged by her. The action now ran to the south-westward with the British battle cruisers circling widely round the enemy, maintaining a range of about 14,000 yards. By 4:5 P.M. the "Scharnhorst" was bearing east on a south-westerly course; she had been hit several times and was listing heavily to port; her superstructure was a mass of ruins, and her speed had been reduced to 12 knots. The smoke was again driving down the range, and at 4:10 P.M. the "Inflexible" to get rid of it turned to starboard and engaged the "Gneisenau" on a north-easterly and opposite course. The "Invincible" did not follow her but ran on to the south-eastward. The end was now near. At 4:17 P.M. the "Scharnhorst" heeled completely over to port; her stern rose steeply in the air and she went down. As she disappeared the "Invincible" turned to starboard and ran to the northward for ten minutes, then ordering the "Inflexible" to take station astern, and turning to port at 4:30 P.M. shaped course to the westward. The "Gneisenau" was some 13,000 yd. to the south-eastward, still struggling along on a south-westerly course. No sooner had the "Inflexible" formed astern of the flagship than the range was again obscured by smoke, and finding it impossible to see the enemy she turned 14 points to port at 4:45 P.M., and leaving the flagship ran to the eastward towards the enemy, opening on him with her starboard guns before the beam and turning to the south-westward at 4:55 on his starboard quarter at 10,000 yards. The "Invincible" meanwhile held on, and turning to the south-westward at 4:52 kept the "Gneisenau" on her port beam at about 12,000 yards. The "Gneisenau" was now under a heavy concentrated fire. By 5:15 she was in a sorry plight. The after turret was out of action, the foremost funnel gone and the ship was barely making headway. A drizzling rain had commenced to fall. At 5:30 P.M. the "Inflexible" ceased fire under the impression that she had struck, but the enemy's fore turret still maintained the contest. At 5:45 P.M. she fired her last shot. She had received some 50 hits and was sinking slowly. At 6 P.M. she went down, stern first. The British battle cruisers rescued 188 survivors from the icy water.

The German light cruisers when they left the squadron had headed south at full speed with the "Kent," "Cornwall" and "Glasgow" in pursuit. When the chase began, the "Nürnberg" was the centre ship, with the "Leipzig" about a mile on her starboard beam, and the "Dresden" ahead about four m. on the port bow. The speeds attained by various ships are difficult to ascertain with absolute certainty. The "Leipzig" was the slowest ship and was probably unable to go more than 20½ knots; the "Dresden" was the fastest and was able to go about 25½ knots, and possibly something over, while the "Nürnberg" could probably go 22. All the German ships had been cruising continuously for four months with no facilities for repair, and probably found it difficult to maintain their speeds. On the British side, the "Glasgow" could go 25½ knots, and the "Cornwall" and "Kent" can be credited with 22½ and 22 knots respectively. There could be no doubt as to the sequel once the British armoured cruisers got within range. The Germans had nothing heavier than the 4·1-in., good guns for their size but no match for the 14 6-in. carried by the armoured cruisers. When the German light cruisers broke off at 1:25 P.M. and the chase began the British cruisers were some 10 to 11 miles behind them. The "Glasgow" did not turn after them till 1:33 P.M., then going 24 knots she overhauled the "Kent" and "Cornwall" and crossed their bows.

According to German accounts Capt. Luce was overhauling the "Dresden" slowly for a time, but at 2:53 P.M. when some four m. ahead of the armoured cruisers he yawed and opened fire with his 6-in. guns on the "Leipzig," damaging one of her ventilating fans, which brought the steam pressure down. The armoured cruisers were now gradually creeping up, and about 4 P.M. the enemy cruisers began to scatter, the "Dresden" going off to the south-west, the "Nürnberg" to the south-east, and the "Leipzig" continuing to the southward. Capt. W. M. Ellerton of the "Cornwall" immediately arranged with Capt. J. D. Allen of the "Kent" that he would take the "Leipzig," leaving the "Nürnberg" to the "Kent." This left the "Dresden" to the "Glasgow," but Capt. Luce thought her speed too great and preferred to remain with the armoured cruisers.

About 4:15 P.M. the "Kent" opened fire on the "Nürnberg" and the "Cornwall" on the "Leipzig," and by 4:30 the latter was being straddled. The "Glasgow" now definitely abandoned all attempt to follow the "Dresden," which disappeared about 5 P.M. in a squall of rain. Turning to the eastward at 4:27 P.M. she passed astern of the "Cornwall," bringing her broadside to bear on the "Leipzig." The chase continued to the south-eastward, for half an hour the "Cornwall" keeping the enemy on the starboard bow, and steering a more easterly course to keep her guns bearing. About 4:50 the "Leipzig" turned to the south-west, and the "Cornwall" following suit had her now on the port bow and brought her port guns into action. The "Leipzig" was now beginning to suffer from the effects of the combined fire, and the "Cornwall" and "Glasgow" had no difficulty in keeping her at ranges of 9,000 to 10,000 yards. By 6 P.M. rain was falling, and as the target was becoming indistinct Capt. Luce made a signal to close. The "Cornwall" now began to fire lyddite with immediate effect. By 6:35 P.M. the "Leipzig" was blazing fore and aft, though still firing fitfully and going some 15 knots. At 7 P.M. her mainmast and her funnels had gone and she was practically only a burning wreck, though her flag still flew defiantly at the foremast. After opening the seacocks about 150 of her crew mustered amidship

hoping to be saved. But as she made no sign of surrender the "Glasgow," after waiting half an hour, closed and opened fire again with terrible effect on the men gathered on her decks. Two green lights went up which were read as a signal of surrender and boats were lowered to perform the work of rescue, but she was heeling heavily to port, and at 9:23, while the boats were approaching, turned over and disappeared, some 80 m. south of the spot where her flagship had sunk five hours before. Only five officers and thirteen men were saved. The British cruisers had suffered little. The "Cornwall" had been hit 18 times, and had a list to port, but had suffered no casualties. The "Glasgow" had been hit twice with one man killed and four wounded. The "Kent" all this time had been vigorously pursuing the "Nürnberg" to the south-east. She had started some seven miles behind her, but the engine-room staff performed prodigies, and by feeding the fires with all the spare wood in the ship the range was brought down to 12,000 yd. by 5 P.M. The "Nürnberg" now opened fire with her stern guns. The "Kent's" shots were falling short, and mist and rain were seriously reducing the visibility. Within the next quarter of an hour however, the "Kent" scored a couple of hits, one of which penetrated the "Leipzig" below the waterline aft and did serious damage. Then came a dramatic change. Two of the "Nürnberg's" boilers gave out, her speed dropped to 19 knots and the "Kent" commenced to overhaul her rapidly. At 5:45 the "Kent" was on her port quarter some 6,000 yd. off, and the "Nürnberg" turned to port to engage her. There was no time to lose in the failing light and Capt. Allen forced the pace. Keeping the enemy well abaft the beam to avoid torpedo fire he closed in to 3,000 yards. The pace was too hot for the "Nürnberg" and she turned right away at 6:02. But the "Kent" followed her close. By 6:10 the enemy was on fire with only two guns in action; the "Kent" continued to hit, and circling right round her bows raked her at 3,500 yards. By 6:25 she was a burning wreck, listing heavily and down by the stern, but with her flag still flying. The "Kent" opened fire again and the flag came down. Just before 7:30 she turned over and sank, but though a search was kept up till 9 P.M. only seven survivors were found. The "Kent" had been hit 40 times, but suffered little structural damage and lost only four killed and 12 wounded.

Meanwhile the colliers "Santa Isabel" and "Baden" had been found by the "Bristol," who had chased them to the southward and eastward and captured them about 4 P.M. They were valuable ships, but Adml. Sturdee had given orders to sink all transports, and though they were not transports but ships full of valuable coal they were sunk. The supply ship "Seydlitz" got off to the southward and found safety amongst the icebergs. The "Dresden" reached Magellan Straits on Dec. 10 and anchored in Cockburn Channel with only 150 tons of coal left. Thence she made for Punta Arenas, where news came of her on the 12th, though three long months elapsed before our cruisers could hunt her down.

This was the end of the chase and the encounter known as the battle of the Falklands. It was the one decisive naval battle of the war—the end of von Spee's squadron, of von Spee, and of both his sons. It marked the termination of a definite phase of the struggle at sea. Cruiser warfare collapsed. Germany could no longer challenge the control of the outer seas, and outside the North Sea and Baltic the command of the sea was won.

(A. C. D.)

**FARNELL, LEWIS RICHARD** (1856– ), English classical scholar and archaeologist, was born at Salisbury Jan. 10 1856. Educated at the City of London school and Exeter College, Oxford, he was elected fellow of his college in 1880 and subsequently rector in 1913. In 1920 he became vice-chancellor of the university. After graduating he studied classical archaeology at the universities of Berlin and Munich, and travelled much in Greece and Asia Minor. In 1909 he was elected the first Wilde lecturer in comparative religion, and he was Hibbert lecturer in 1911. He published *Cults of the Greek States* (5 vols., 1896); *The Evolution of Religion* (1905); *Greece and Babylon* (1911); *The Higher Aspects of Greek Religion* (1912).

**FARRAND, LIVINGSTON** (1867– ), American educationist, was born at Newark, N.J., June 14 1867. After graduation from Princeton in 1888, he studied medicine at the College of Physicians and Surgeons, New York, and received the degree of M.D. in 1891. During the next two years he studied at Cambridge (England) and at Berlin. From 1893 to 1903 he taught psychology at Columbia University as instructor, and, after 1901, adjunct professor; from 1903 to 1914 he was professor of anthropology. In 1897 he accompanied the Jesup North Pacific Expedition, which visited the Indians of British Columbia, and published two monographs as results of his own investigations. From 1905 to 1914 he was executive secretary of the National Association for the Study and Prevention of Tuberculosis; and from 1912 to 1914 was treasurer of the American Health Association, during the same period editing the *American Journal of Public Health*. From 1914 to 1919 he was president of the university of Colorado, but in 1917 was granted leave of absence, following his appointment by the International Health Board of the Rockefeller Foundation to direct the work against tuberculosis in France. In 1919 he was made chairman of the Central Committee of the American Red Cross. In 1921 he was elected to succeed Jacob Gould Schurman as president of Cornell University. He was the author of *Basis of American History* (1904) and various articles on psychology and anthropology.

**FARWELL, SIR GEORGE** (1845–1915), English judge, was born at Codsall, Staffs., Dec. 22 1845. He was educated at Rugby and Balliol College, Oxford, where he took his degree in 1866. He was called to the bar in 1871. In 1891 he became a Q.C. and in 1895 a bencher of Lincoln's Inn, while in 1899 he was raised to the bench. In 1900 he came into prominence over the case known as the Taff Vale judgment (*see* 27.142), since his decision, though reversed by the court of appeal, was upheld in 1901 by the House of Lords, and ultimately led to the passing of the Trade Disputes Act (1906). In 1906 Farwell was made a lord of appeal, but resigned this position in 1913. He died at Dunster, Som., Dec. 30 1915. He published *Concise Treatise on the Law of Powers* (1874).

**FASTING** (*see* 10.193).—The adoption of "hunger-striking" in prison by some of the militant suffragettes in England, just before the World War, and by Irish Sinn Feiners subsequently, has served to call attention to the physiological fact that the human body is capable of more prolonged fasting (abstinence from food) than had generally been realized. Before they gave these demonstrations of endurance, fasts of 40 or 50 days had been regarded as extreme cases. In 1920, however, the Lord Mayor of Cork, Terence McSwiney, maintained his hunger strike in Brixton prison during 74 days, and, though subject to fits of delirium, he was stated to have been conscious until within a few days of his death.

From a purely scientific point of view it is regrettable that no definite medical record of this and other long "hunger strikes" was officially published, in such a way as to provide positive evidence that no "food" (apart from water and medicines) was taken, since there were naturally suspicions to the contrary in spite of all questions in Parliament on that point being answered in the negative. It can only be assumed that such allegations were unfounded. It has been shown therefore that, if the hygiene of fasting is carefully carried out, the mere lack of food becomes of small moment to the preservation of life for several weeks. The beginning of a fast is its most painful period, for during the first 48 or 36 hours hunger pains, occasioned by peristaltic contractions of the stomach, persist. These pains at first increase in severity during some hours, then, if no food is taken, they begin to pass away. Once they have disappeared they do not, as a rule, return. The fasting individual passes into a condition of comparative ease and comfort. The future now depends on the care with which the debris, collecting in the alimentary canal, is evacuated—for the bowel goes on producing waste matter in spite of the absence of food. Purgation is therefore necessary, and enemata are usually administered. The skin tends to exude an oily detritus, and unless this is removed constantly a fecal odour will be experienced. Here again, however, the beginning is the worst period. After some days the problem of maintaining health is much simplified, and the patient, though increasing in weakness, experiences small inconvenience. This period is, however, often characterised by hallucinations, the mind being dissociated from its material surroundings. Visions are frequently described and strange manifestations announced. The patient is now approaching the

time when he must break his fast or die. Recent investigation suggests that death will be due to acid poisoning, and it is stated that the administration of what are called "buffer salts," for example the acid phosphate of sodium, is instrumental in postponing the fatal issue. In any case the end is apt to occur suddenly, the patient becoming collapsed without warning. If the fast is broken with a little fruit juice and then milk given for a day or two no untoward results seem to follow. Indeed, many people derive benefit and practise occasional fasting for a short period as a therapeutic measure. The Allan treatment of diabetes is an instance in point. There are many cases on record of men walking considerable distances on the 40th day of a fast, and shorter fasts have been fairly common. It need scarcely be added that water is taken throughout the period of abstinence in all instances. (R. M. Wi.)

**FAWCETT, MILLICENT GARRETT** (1847– ), British writer and political worker, was born at Aldeburgh, Suffolk, June 11 1847, the seventh child of Mr. Newson Garrett. In 1867 she married the economist Henry Fawcett, subsequently Postmaster-General (*see* 10.215), and during her husband's life was closely associated with him in all his work, his blindness making him in many ways extremely dependent upon her. She herself produced various works on economics, including *Political Economy for Beginners* (1870), *Tales in Political Economy* (1875), and, with her husband, a volume of *Essays and Lectures* (1872). Mrs. Fawcett had for many years been interested in the higher education of women and in their economic and political future, and was one of the early workers for women's suffrage, becoming more prominent in the cause after her husband's death (1884). By about 1870 various small societies had grown up with the purpose of advancing the cause of women's suffrage, and in 1896 these were amalgamated under the name of the National Union of Women's Suffrage Societies, Mrs. Fawcett in 1907 becoming the president of this movement. The body was for some years the only important suffrage society, and most of the pioneers of the movement belonged to it; but in 1906 the Women's Social and Political Union was formed, pledged to work by militant, as opposed to constitutional methods. Mrs. Fawcett was strongly opposed to the tactics of the militant suffragists, and expressly dissociated the N.U.W.S.S. from any sympathy with such methods. The constitutional methods adopted by the body of which she was president included an alliance formed with the Labour party (1912) by which the society agreed to support Labour candidates in preference to Liberal when the latter proved unsatisfactory on the suffrage question. Mrs. Fawcett in 1912 produced her work *Women's Suffrage*, and her other books include *Lives* of Queen Victoria (1895) and Sir William Molesworth (1901), and *Five Famous French Women* (1906).

Mrs. Fawcett's only child, Miss Philippa Garrett Fawcett, had a distinguished career at Newnham College, Cambridge, where in 1890 she was bracketed equal to senior wrangler. She became in 1905 principal assistant in the Education Officer's department of the L.C.C.

**FAYOLLE, MARIE-EMILE** (1852– ), French marshal, was born at Puy (Haute Loire) May 14 1852. He entered the École Polytechnique in 1873, and on leaving in 1875 was posted to the 16th Regt. of artillery. As a subaltern he saw service in Tunis. He was promoted captain in 1882. In 1889 he passed through the École de Guerre, to which, in Nov. 1889, he returned as assistant to Col. Ruffey, who was then artillery lecturer. At this time Foch was lecturer in tactics, and Maud'huy and Pétain joint lecturers in infantry. In 1900 Fayolle succeeded Ruffey as artillery lecturer and held the appointment for seven years. He was promoted lieutenant-colonel in 1902 and colonel five years later. In Nov. 1908 he took over command of a regiment of artillery, and in 1910 he was made a general of brigade; but as on May 14 1914 he had passed the age limit and had not received further promotion he was placed on the retired list. On the outbreak of the World War he was recalled and given command first of a reserve brigade and then of the 70th (Reserve) Division. This division took part in the abortive Lorraine offensive of Aug. 1914. It distinguished itself in the defence of Nancy and was made the subject of a special order of the day by de Castelnau. In Oct. 1914 the division again received special notice—this time for the part it played in the fighting on the line Gavrelle–Bailleul. On Oct. 11 Fayolle was made a Commander of the Legion of Honour. In June 1915 the division was again made the subject of a special army order by Gen. d'Urbal who commanded the X. Army. On May 13 1915 Gen. Fayolle had been, contrary to the custom in the case of retired officers and in face of considerable opposition, promoted a temporary general of division. In June of the same year he succeeded Gen. Pétain in the command of the XXXIII. Corps. On Feb. 26 1916 he was promoted to the command of the VI. Army, and on March 25 following was confirmed in his rank as general of division. In command of the VI. Army, he carried out the French portion of the Somme offensive (July 1916–Nov. 1916). On Oct. 8 1916 Fayolle was made a Grand Officer of the Legion of Honour. In May 1917 he again succeeded Pétain, this time in the command of the centre group of armies. In Nov. he went to the Italian theatre in command of the French forces that were sent thither after the disaster of Caporetto. He returned in Feb. 1918 and took an important part in repelling the German offensives of March–June 1918, and in the Allied counter-offensive from July 18 onwards as commander of the northern group of armies. On July 10 he was given the Grand Cross of the Legion of Honour. Somewhat tardily he was, in Oct. 1919, awarded the Médaille Militaire. But not long afterwards he was, with Lyautey and Franchet d'Espérey, given the highest grade of all, that of Marshal of France.

**FAZY, HENRI** (1842–1920), Swiss statesman and historian, was a member of a family which at the date of the Revocation of the Edict of Nantes (1685) came from Dauphiné to Geneva to seek protection for religious reasons. Its most prominent member was his great-uncle, the Radical statesman, James Fazy (*see* 11.591), whose biography (1887) was written by him. He was born at Berne on Jan. 31 1842. He studied at Geneva for his doctorate in philosophy and law, became a member of the Genevese cantonal parliament in 1868, and was member of the cantonal executive from 1897 till his death. He was a Radical in politics, but of a more moderate type than his great-uncle, and founded a Radical "group," opposed to the more extreme section. Carteret, the successor of James Fazy as leader of the latter, died in 1889, and henceforward Henri Fazy played a more and more prominent part in Radical Genevese politics. As a member of the cantonal executive he had charge of the Department of Finances, and was much criticised by Gustave Ador, the leader of the Democrats or Whigs. In 1880 his proposal to separate Church and State in Geneva was rejected by the people, but was finally accepted by them in 1907. He was a member of the Swiss Conseil National from 1896 to 1899, and from 1902 onwards. After the Radical defeat of 1918 he was the only member of his party who was not turned out of office, but he became more and more conservative as time went on. In 1914, as the senior member of the Swiss Conseil National, he protested solemnly against the violation of the neutrality of Belgium.

For many years he was the archivist of Geneva, and also professor of Swiss history at the university of Geneva (1896–9 and from 1902). In the latter capacity he wrote much on Genevese history. In 1887 appeared the *Life of James Fazy*, in 1890 the *Constitutions de Genève*, in 1891 *L'Alliance de 1584 entre Berne, Zurich et Genève*, in 1895 *Les Suisses et la Neutralité de Savoie*, in 1897 *La Guerre du Pays de Gex et l'Occupation genevoise, 1589–1601*, in 1902 *Histoire de Genève à l'Époque de l'Escalade, 1589–1601*, in 1909 *Genève et Charles Emmanuel* and countless papers in the *Proceedings* of the Institut National Genevois. He died at Geneva Dec. 22 1920.

**FEBVRE, ALEXANDRE FRÉDÉRIC** (1835–1916), French actor (*see* 10.231). He retired from the Paris stage in 1893, and made a final tour of certain European capitals the following year. He died in Paris Dec. 14 1916.

**FEDERAL FARM LOAN SYSTEM (United States).**—The Federal Farm Loan Act of 1916 was adopted in the United States for the following reasons. Increasing use of costly equipment and the rising price of farm land had combined to make the problem of financing the American farmer a difficult one. His need for short-time credit, generally, had been met in various

ways. Country merchants frequently advanced supplies to a farmer and received their pay after his crop was marketed. Manufacturers of farm machinery and of fertilizers also did a large credit business. A great many small country banks had sprung up since 1890 whose chief function was to supply short-time credit to farmers. The chief difficulty, however, was to supply long-time or mortgage credit. When the farmer must make a heavy investment, he needs a long loan. The only satisfactory security he can offer is a mortgage, and the market for farm mortgages is limited, because comparatively few persons with money to lend are experts in farm values or otherwise in a position to deal safely in farm mortgages. This difficulty was accentuated in new communities by the lack of local lenders with sufficient expertness. It had in the past been partly, but only partly, overcome in various ways. Local mortgage brokers or banks having the necessary expertness, could lend on a limited number of mortgages, and after adding their own endorsements, discount the loans with eastern investors. In other cases, some of the large insurance companies sent their own experts into selected regions to place loans secured by mortgages. Again, a number of large corporations, commonly called mortgage banks, were organized to lend on mortgage security and to sell their own bonds to the investing public. Such a corporation, having bought a number of mortgage notes aggregating $100,000, would deposit them with a trustee as security for its own bonds to the same amount. These bonds were then sold to the general investing public, but sold on the general reputation of the corporation issuing them, and not on the buyer's expert knowledge of the individual mortgages.

In order to extend this principle and enable it to meet the need for mortgage credit throughout the country, the Federal Farm Loan Act of 1916 was passed. This Act created a Federal Farm Loan Board, to consist of the Secretary of the Treasury and four others to be appointed by the President, and to have general administrative control of the system. Under this Board there were created 12 farm land banks, located in the 12 different districts into which the country was divided, each bank to be the centre of the farm loan system for its own district. In each district there were to be organized, under its farm land bank, an indefinite number of farm loan associations, composed wholly of farmers desiring to borrow money on mortgage; and they borrow from the farm land bank of their district.

The 12 Federal farm land banks are located in the following cities:—Springfield, Mass., Baltimore, Md., Columbia, S.C., Louisville, Ky., New Orleans, La., St. Louis, Mo., St. Paul, Minn., Omaha, Neb., Wichita, Kan., Houston, Tex., Berkeley, Cal., Spokane, Wash. There was also a provision in the Federal Farm Loan Act permitting joint stock mortgage banks, such as those already described, to come in under the Federal farm loan system. Twenty-five had done so before Feb. 15 1921, with capital stock of $7,966,000, with bond issues aggregating over $76,000,000, and with loans to farmers aggregating almost $78,000,000. Every Federal farm land bank was required to have, before beginning business, a subscribed capital stock of not less than $750,000. This provided the initial fund from which to purchase the first batch of mortgages from the farm loan associations. Additional funds were to be raised through the sale of bonds to the investing public. Each issue of bonds was to be based upon a batch of mortgages previously purchased and deposited as security under the direction of the farm loan board. In order to assure a sufficient amount of capital stock, it was provided that in case the total $750,000 of capital stock of any Federal farm land bank was not subscribed within 30 days after the opening of the books, it was made the duty of the Secretary of the Treasury "to subscribe the balance thereof on behalf of the United States." In order still further to assure the farm land banks a working capital, in case the public was slow to invest in the farm loan bonds, amendments were passed (Jan. 18 1918 and May 26 1920) authorizing the Secretary of the Treasury to purchase $200,000,000 of such bonds during 1918–21.

On Dec. 31 1920 the U.S. Government held $6,832,680 of the capital stock of the farm land banks and their bonds to the amount of $182,235,000. The total bonds authorized and issued by them was $333,784,500. The total capital stock of the 12 farm banks amounted to $24,591,515 held as follows:—

| | |
|---|---|
| By the U.S. Government | $6,832,680 |
| By National Farm Loan Ass'ns. | 17,663,725 |
| By borrowers through agents | 79,230 |
| By individual subscribers | 15,880 |

The total amounts loaned by the 12 Federal land banks up to Nov. 30 1920 were as follows:—

| | |
|---|---|
| Springfield | $13,550,345 |
| Baltimore | 14,732,783 |
| Columbia | 20,406,515 |
| Louisville | 27,691,200 |
| New Orleans | 25,811,705 |
| St. Louis | 30,951,675 |
| St. Paul | 49,554,700 |
| Omaha | 48,905,890 |
| Wichita | 31,531,300 |
| Houston | 40,754,766 |
| Berkeley | 18,645,900 |
| Spokane | 46,084,535 |
| Total | $368,621,314 |

Under the operation of this Act and its amendments, such moneys as are secured from the sale of bonds, either to the Secretary of the Treasury or to the investing public, are loaned by the farm land bank to farm loan associations within its district in return for mortgages given by individual farmers to these farm loan associations. The course of the money is, therefore, as follows: first, from the investor to the farm land bank in exchange for bonds; second, from the farm land bank to the farm loan association in exchange for a batch of mortgages; third, from the farm loan association to the individual farmer in exchange for an individual mortgage. The securities, however, proceed in the opposite direction; first, a mortgage is given by the individual to his local farm loan association in exchange for money; second, this and other similar mortgages are transferred from the farm loan association to the farm land bank in exchange for money; third, the farm land bank deposits these mortgages under the direction of the Federal farm loan board and, on that security, issues its own bonds and sells them to investors.

It was provided in the Farm Loan Act that the bonds of the farm land banks were to be exempt from taxation. The purpose of this exemption was to make such bonds so attractive to the general investor as to compensate for a low rate of interest. This low rate of interest on the bonds would then enable the farm land banks to accept farm mortgage notes paying a low rate of interest, and thus the farmer would be able to borrow at a lower rate than would be necessary if the farm loan bonds were subject to taxation. Those issued prior to May 1 1920 paid 4½%. Subsequent issues pay 5%. This provision was bitterly attacked on the ground that it was class legislation, or discrimination in favour of farmers as against other classes. The matter was under litigation for many months, but finally in Feb. 1921 the Supreme Court decided in favour of the constitutionality of the Act. (T. N. C.)

**FEDERAL RESERVE BANKING SYSTEM.**—The Federal Reserve Banking System of the United States is the outgrowth of a movement for what was called "banking reform," which had been in progress for about 20 years prior to the enactment of the Federal Reserve Act on Dec. 23 1913.

The National Banking System, which in 1913 contained a total of about 7,500 members, had been organized during the Civil War, the constituent Act being passed in 1863 and modified in the following year. It provided for the creation of independent institutions operating under the general requirements of the National Banking Law, but organized directly at the will of prospective stockholders. The fundamental basis of the law was "free banking," as reflected in general authority to organize banks provided that the capitalization of each institution should not be less than a specified sum varying with the population of the place in which the proposed bank was to be situated. The minimum of capitalization was $50,000 (changed in 1900 to $25,000). Currency issued by the national banks was based upon and protected by Government bonds which each bank was required to purchase in a specified amount, not exceeding, however, a sum equal to the capital of the bank. Bond purchase provisions were later modified, but the essential principle remained. When these bonds had been purchased they were deposited with the Treasurer of the United States who thereupon issued circulating notes to the bank. Each bank was required to maintain a specified reserve which amounted to 25% in the case of banks located in three central reserve cities (New York, Chicago and St. Louis),

while in reserve cities (eventually nearly 50 in number) the requirement was 12½% cash in vault and 12½% in the form of balances in banks in the central reserve cities. All other banks were required to keep 15% reserve, of which 6% had to be cash in vault and 9% might be in the form of balances in the banks of central reserve cities.

This system had proved inadequate because in time of stress or panic there was no recognized means for relieving hard-pressed banks; also the currency was inelastic, being limited by the amount of bonds available, and being slow in its issue and even slower in redemption. During and shortly after the panic of 1893, an agitation was started in favour of some plan for the issue of "emergency currency" as a means of preventing the development of acute panics; this ultimately grew into a demand for a currency not purely of emergency nature but elastic as required by business needs, and therefore including issues of ordinary bank-notes protected by the joint guarantee of the banks. The only practical outcome of this agitation was seen in certain sections of the Gold Standard Act of 1900. These provided for refunding the outstanding U.S. bonds at a rate (2%) which precluded the growth of a premium while it authorized banks of $25,000 capital in places with less than 3,000 people. Both provisions tended to make the issue of notes easier. Although numerous bills were urged, especially after 1907, the proposed plan for a really elastic note issue was never seriously considered by Congress because of the unwillingness of the larger banks to guarantee notes issued by a great many small institutions. After the panic of 1907 the so-called Aldrich-Vreeland Act was adopted (May 30 1908). This made provision for the organization of "national currency associations" which would have been allowed to issue notes based upon commercial paper or other securities deposited by constituent banks with the associations in question. At the time, however, the plan did not get into practical operation, partly because the difficulties attendant upon the panic of 1907 had been overcome before the Act was enacted. Contemporaneously with the Aldrich-Vreeland Act, provision was made for the creation of a body called the National Monetary Commission, which continued investigations for several years and eventually proposed a bill for general banking reform, ordinarily described as the Aldrich bill. This measure contemplated the creation of a central banking organization with branches. The plan still retained the fundamental concept of an emergency currency, but the proposed institution was not equipped with the ordinary powers, duties and responsibilities which had been found necessary in central banking experience abroad. It has been supposed that the Aldrich bill would have been adopted in its original or a modified form if the Republican party, under whose auspices it had been developed, had not been defeated in Nov. 1912. The Democratic party having come into office in the spring of 1913, the duty of enacting banking legislation was necessarily assumed by it and in June of that year a bill embodying what afterward became the Federal Reserve Act was introduced into congress. The measure had been under construction and preparation from about March 1912 onward, and a first draft of it had been presented to President-elect Wilson soon after the election of 1912. It was then approved by the President-elect, and the process of perfecting and improving it went on during the winter of 1912–3 under direction of a House of Representatives Committee. This bill when introduced had thus been under consideration at the hands of the special committee of the House Banking and Currency Committee for about 15 months prior to the date of its introduction, while preliminary studies had been undertaken even earlier. The bill consequently was quickly completed, went through Congress during the middle of 1913 and became law on Dec. 23 of that year.

*Theory of Federal Reserve System.*—The theory of the Federal Reserve Act was the separation of the central banking functions of the past from practical bank operation, the latter being carried on through distinct reserve banks under the general direction of a board vested with the banking functions of the past. To carry out this idea, the Federal Reserve Act provided for the creation of a number of central institutions whose membership was to consist of national banks, while institutions organized under state law (banks and trust companies) might at will also become members. Each such bank was obliged to contribute a sum equal to 3% of its capital and surplus and to become liable for an additional 3% which might be called in case of necessity. The central directing mechanism of the system was the Federal Reserve Board, which consisted of five members chosen by the President of the United States with the Secretary of the Treasury and the Comptroller of the Currency as members *ex officio*. No two of these five selected members were to be chosen from the same Federal Reserve district. An essential and fundamental requirement of the Act was the compulsory transfer of the reserves of member banks to the Federal Reserve banks, the reserve provisions requiring a minimum of vault cash and a minimum of balances on the books of the Federal Reserve bank, while a certain percentage of the required reserve might be either in vault or in the Federal Reserve bank. This was the so-called "divided reserve." The maximum required reserve (in central reserve cities) was 18%, of which 5% was to be in vault, 6% with the Federal Reserve bank, and 7% either in vault or with the reserve bank at the discretion of the member. Each reserve bank was authorized to issue currency protected by notes and bills growing out of commercial, industrial or agricultural operations. These notes and bills were to have a maximum maturity of 90 days, except where they were the product of agricultural transactions, in which case the maturity was raised to 180 days. Deposits of these notes were to be made with an officer known as the Federal Reserve Agent, there being one such officer at every Federal Reserve bank. Each Federal Reserve bank was governed by a board of directors, six of whose members (three bankers and three business men) were chosen by constituent member banks voting in three separate groups according to size of capital, while three (including the Federal Reserve Agent who was also the chairman) were chosen by the Federal Reserve Board. The Federal Reserve Board was given the function of passing on and establishing rates of discount, such rates, however, being originally named by the boards of directors of the several Federal Reserve banks. The task of dividing the country into districts was placed in the hands of an organization committee with instructions to establish not less than eight nor more than twelve such districts. This committee eventually divided the country into 12 districts with a Federal Reserve bank in each, and the President of the United States named the Federal Reserve Board in accordance with the new law, the new organization taking office Aug. 12 1914. On coming into existence, the board proceeded to organize a Federal Reserve bank in each district; the member banks paid in their stock subscriptions Nov. 2, and the Federal Reserve banks opened for business Nov. 16 1914. As thus organized the initial paid-in capital of the system at opening was about $18,000,000, while the gross reserve balances were $256,000,000. These balances at the outset were obtained chiefly through actual transfers of specie and legal tender money ($205,000,000), although in some cases rediscount credits were granted to aid members in establishing the necessary legal balance. Each bank was at the outset equipped with a small staff of officers and employees and a uniform accounting system. The beginning of the year 1915 found the system in operation, but with its transactions upon a small scale. Its first duty was to aid in the retirement of the emergency currency which had been issued shortly after the opening of the World War under the terms of the Aldrich-Vreeland Act, as modified by Congress just after the outbreak of the war in such a way as to render the working of its provisions rather more flexible than was possible under the original legislation. At the outset, however, the system was of considerable service in controlling the outflow of gold which had proved to be an embarrassing feature of the economic changes that immediately succeeded the opening of the war, while it also aided in other emergency measures. Various measures were adopted with this end in view the best known being the so-called hundred-million-dollar "gold pool" formed after the outbreak of the war to provide exchange and to check gold losses.

*Operation of the System.*—The operation of the Federal Reserve System may be divided into three distinct periods, the first from Nov. 2 1914 to the declaration of war by the United States April 6 1917; the second extending from the latter date to a period some time after the conclusion of the Armistice of Nov. 11 1918 (the date most aptly chosen for the close of this period probably being Nov. 4 1919); while the third period extended from the latter date to the close of the year 1920. During the first or pre-war period the functions of the system were concerned largely with the organization of its own constituent units and the modification of banking practice in the United States and with the establishment of methods suited to the initiation of the new plan. These functions naturally fell into two main groups: (1) in the internal organization of the Federal Reserve banks, and (2) in the establishment of satisfactory relationships between them and their members. In the latter category should be placed the work done in perfecting coöperation between the banks and the clearing houses of the different communities and in developing methods of collection, in working out plans for rediscounting with the least possible delay and friction, and other matters of equal importance. In the same group of functions must also be placed the work done by the Federal Reserve System in developing a new standard for commercial paper. The Federal Reserve Act had given to the Federal Reserve Board the duty of defining commercial paper. Consequently, one of the first undertakings of the board was the establishment of regulations designed to cover the different classes of commercial paper and the processes to be pursued by reserve banks in discounting such paper. These regulations did not have the force of law since they merely amounted to a statement of the standards with which commercial paper must comply in order to be "eligible," that is to say, to be rediscountable at the Federable Reserve banks. Nevertheless, the growing power of the Federal Reserve banks was such that these standards of eligibility rapidly came to be recognized through the whole of the banking community. Progress was made in the matter of securing nearly identical methods of preparing financial statements to be used for the purpose of testing the credit position of firms who were presenting paper for discount. An outstanding element in the work of the Federal Reserve Board during this first period was the national and district clearance and collection system. The Federal Reserve Act had authorized the board to act as a clearing house for the several reserve banks, and early in 1915 the board took action by establishing the so-called Gold Settlement Fund at Washington. Each bank contributed originally a sum of $1,000,000 in gold, the entire amount being stored in the Treasury or the sub-treasuries. Claims accumulated by reserve banks upon one another were each week telegraphed as an aggregate to the board at Washington and offset against one another, the net debit or credit balances in the fund being registered in a set of books created for that purpose. The size of the fund grew rapidly and eventually reached a maximum of about $500,000,000. A second section of the fund was established to provide for clearances growing out of the accounts of Federal Reserve Agents as distinct from the bank to which they were accredited. The Gold Settlement Fund probably would not have been successful alone had it not been supported by some plan for the collection of items originating within the several districts. Such a plan was, however, worked out and put into effect in practically final form beginning about July 1 1916. This was the so-called "intradistrict" collection system. It provided for the depositing of cheques (at first only on member banks but finally on any other bank or any banker) by members or holders of clearing accounts with Federal Reserve banks. These cheques were sent to the banks upon which they were drawn, the latter being required to remit the proceeds in cash or acceptable exchange or to authorize the charging off of these remittances upon the books of the reserve banks. Member banks, of course, habitually followed the latter plan, while non-members who had no account with the reserve bank were obliged to furnish exchange or send coin. Although there was opposition from the banks which had previously made a profit out of this kind of exchange business, the opposition gradually lessened. Possibly the most vigorous form which it assumed was seen in the amendment to the Federal Reserve Act adopted in 1917, in which exchange charges made by member banks were recognized but which, on the other hand, practically neutralized such charges by providing that the Federal Reserve banks should not be permitted to pay exchange. The matter was promptly tested in the courts, and as a result of favourable decisions and of the evidently beneficial character of the system, the number of banks which agreed to clear at par was extended until in 1920 it included more than 29,000 institutions—practically all the banks of the United States. The total operations of the Federal Reserve intradistrict clearing system were at the rate of $13,124,000,000 per month during the year 1920.

*War Finance.*—Although the Federal Reserve System had practically established itself during the two and a half years of its existence prior to the entry of the United States into the war in April 1917, it was doubtful whether the resources of the system were sufficiently large to enable it to bear the strain which all recognized would be thrown upon it as soon as war demands began to make themselves felt. Accordingly Congress, upon recommendation of the Federal Reserve Board in June 1917, passed an amendatory Act which provided that nothing should be counted as reserve except balances on the books of Federal Reserve banks. The United States had declared war on April 6 1917, and almost immediately thereafter many of the larger State banks and trust companies, which had previously hesitated to become members, filed their applications, actuated partly by patriotic desire to strengthen the Government's accounts and partly by the fact that the severe financial stress of the war would be most easily met by the institutions which had joined the system. This movement into the Federal Reserve System was accelerated through the amendatory Act to which reference has already been made, so that in the course of the year 1917 the resources of the System were enormously increased, while its gold holdings were vastly added to through the gradual withdrawal of coin not only from the vaults of banks but also from circulation. Shortly after the declaration of war the Secretary of the Treasury had placed an issue of $50,000,000 of treasury certificates of indebtedness with the reserve banks, but it was promptly recognized that this plan of financing was unsound; and subsequent issues, both of long-term bonds and of Treasury certificates, were placed with member banks and so far as possible with the public through the reserve banks acting as intermediaries. It was seen from the outset, however, that in order to keep the rate of interest on Government bonds at a low figure and to insure wide distribution of the bonds, it would be necessary to guarantee their holders that they could borrow freely by using them as security at rates which would involve no expense. Consequently, from the date of the First Liberty Loan (June 1917) onward, banks all over the country undertook to loan to their customers on Liberty Bonds such amounts as the customers might need, running up to a total close to the face of the bonds, and at the same time reserve banks undertook to rediscount the notes collateraled with these bonds when received from the member banks. As the Government itself had entered, upon a wide scale, into business enterprises growing out of the war, a large and increasing volume of its payments for supplies, services and other needs was made out of the proceeds of bonds and certificates and this class of paper accordingly superseded in a corresponding degree paper which would otherwise have been made by business men for the purpose of financing their ordinary transactions. Both in order therefore to assist the rank and file of the public in absorbing Liberty Bonds and to facilitate the Government's own operations, there were large additions to the portfolios or holdings of reserve banks and the amount of the notes they issued and the deposits they entered on their books increased rapidly. At the end of 1917 there was outstanding in notes $1,247,000,000 while reserve deposits were $1,446,773,000 and total resources were $3,089,945,000. These conditions were more and more accentuated as the war continued, particularly in view of the fact that the U.S. Government found it necessary to advance large sums to foreign countries, selling Liberty Bonds in order to provide the means for so doing. The consequence was an enormous increase of general prices brought about partly by the steady draft upon the consumable commodities in the country which were exported in great quantities (the total shipments during 1918 being $6,149,087,545 as against $2,484,018,292 in 1913), while they were partly due also to the great increase of bank-notes and bank deposits both on the books of members and of the reserve institutions themselves. It had been hoped that upon the declaration of the Armistice there would be a reaction to more conservative methods of financing, but the enormous commitments which had been made in sending about two million soldiers to France and in taking from the Allied Governments their obligations to a total eventually of about $9,600,000,000, constituted a situation which could not be immediately altered. In fact, war expenses continued to increase for several months after the Armistice, and the floating of a Fifth, or Victory, Loan, early in 1919, was essential in order to fund some part of the immense floating indebtedness of

nearly $10,000,000,000 for advances to foreign countries, fully $2,500,000,000 of such advances being actually paid after the Armistice. The war finance period thus in effect extended to the middle of 1919 at least. By that time, however, the advance of prices was tremendous, and a very serious question arose as to whether the reserve banks ought to announce a material increase in their rates of discount. The objection to their doing so was strongly urged by the Treasury authorities, because such a policy would result in increasing the cost of money to the Government.

*After the War.*—The final conclusion of the operations attendant upon the Fifth, or Victory, Loan created a financial situation which was distinctly better from the standpoint of the Treasury than that which had existed before, and somewhat reduced the opposition of the department to a restoration of normal discount rates. Accordingly in Nov. 1919 a tentative advance in the rate of discount on all classes of commercial paper was made. This had but little effect upon the volume of credit outstanding, although it kept the rate of expansion below that which would otherwise have been unavoidable. Experience during the next six months showed that much more positive action would have to be taken, for speculation continued. It was not so intense in stocks and securities as during the month immediately after the Armistice, but prevailed very widely in staple materials as well as in many classes of finished products. In order to check this development of speculation, it was essential to limit the extension of credit to traders and manufacturers as well as to farm interests, which were seeking to obtain bank accommodation in order to carry large quantities of products which they withheld from the market. The rate of discount was eventually raised in May 1920 to a maximum of 7 per cent. Meanwhile a change in the personnel of the Treasury Department had occurred, and one of the features of the new régime was an alteration of policy with respect to methods of borrowing. The Treasury Department now advanced its offered rate of interest on certificates of indebtedness to a maximum of 6%, a figure more nearly corresponding to the prevailing rate in the open market. These advances took place practically simultaneously with corresponding action by the Bank of England and the British Government. The effect in both countries was beneficial in two ways—it tended to place the Government's obligations more freely in the hands of investors and thus to take them out of the banks, while the advance in discount rates coupled with the initiation of an anti-speculative policy and the withholding of credit from those who desired to hoard and store products tended strongly to bring commodities directly upon the market. The consequence was the administration of a sharp check to the growth of credit, and during the latter part of the year 1920 there was a decided restriction of the total amount of new bank accommodation granted both by the reserve banks and by their members, while there was a very decided reduction in the degree of activity with which bank deposits were used. In addition to these changes in bank position was the fact that the extraordinarily high prices which had ensued upon the close of the war, reaching their peak in May 1920, declined rapidly from the middle of 1920 onward, eventually reaching, at the close of the year, an average level of about 190 as compared with 272 in May and 100 in 1913. This rapid decline tended to curtail the demands upon reserve banks and had the effect of eliminating the borrowing of many concerns which had been conducting operations on an unsound and semi-speculative basis. The close of the year 1920 found the reserve banks with $3,552,922,000 in notes outstanding, with total discounts amounting to $2,687,393,000 and total resources to $6,282,755,000.

*Expansion of Reserve Banks.*—Before the entry of the United States into the war the operations of the Federal Reserve banks had been restricted, for reasons already explained, so that the personnel employed was necessarily limited. It had not been found necessary to expand the number of offices although the Federal Reserve Act had authorized the creation of branches both at home and abroad. Early in the history of the system a branch of the reserve bank at Atlanta had been established at New Orleans because of the importance of that city as a port of communication with South America. This, however, continued for a good while to be the only branch bank in the system. The great expansion of operations resultant upon the fiscal transactions of the Treasury coincided with the upward swing of business which resulted from the complete establishment of the collection system. It was found that greater efficiency could be secured through the opening of new offices at strategic points, and before Jan. 1 1921 there had been created in all 23 branches. These branches varied to some extent in the scope and character of their functions, certain of them acting primarily as collection agencies while others added thereto very considerable powers in the rediscounting of paper and the holding of reserves. In some cases, as on the Pacific coast, creation of branches resulted from the fact that the district in which they were situated was so large that as a mere matter of convenience it was desirable to establish some local offices. In other cases the creation of branches grew out of peculiar local conditions or a need for recognition of the importance of some industrial centre outside the city in which the parent bank was situated. The local branch offices were usually given a comparatively simple organization and wherever possible the effort was made to have them practically dependent upon the bank of the district. To facilitate this closeness of relationship and also to ensure prompt action in connexion with clearance and rediscounting operations a leased wire system, including both telegraph and telephone, was put into operation between the various banks in 1917, uniting the whole series of parent offices and branches with the board in Washington and rendering possible practically instantaneous communication upon matters of business policy. While it was never deemed expedient to establish actual branches in foreign countries, the system early in the war entered into agency relationships with the Bank of England whereby that institution was to hold funds in trust for the Federal Reserve banks jointly while they in turn were to undertake similar duties for the Bank of England. It was understood at the time that the agency relationship would not, until after the war at least, lead to the performance of functions involving the buying and selling of bills or operations in the discount market. Similar relationships were later concluded with the Bank of France, the Bank of Japan and various other international institutions, but in all cases the relationship was on a restricted basis and never resulted in the undertaking of international discount operations. From the opening of the war onward, the personnel of the Federal Reserve banks expanded very rapidly, as was necessary in order to comply with the heavy demands that were made upon the banks for services. For the year 1920 the personnel of the banks probably averaged about 10,000 persons, while their combined earnings for that year were $181,000,000, and their total expenses of operation, $29,889,000, or about 16½ per cent. Earnings which had been small before the war, some banks barely making expenses and others paying a little less than the 6% dividend provided for in the Act, shot up rapidly, as the result of heavy Government loans and the large advance made by the reserve banks in connexion therewith. For the year 1920 the earnings of the entire system, after setting aside all reserves, providing for depreciation, etc., were well over 200% on the capital. This, of course, was an abnormal condition resulting from the financing of the war period and corresponding to similarly heavy earnings at the central banks of foreign countries. Under the terms of the original Federal Reserve Act all earnings above 6% on the capital stock were to be transferred to the Government in lieu of a franchise tax. The receipts of the Government in the form of profits from the Federal Reserve banks, therefore, from the beginning to the close of 1920 amounted to about $150,000,000.

*Influence of Reserve Banks on Banking and Business.*—The influence of reserve banks upon business conditions in the United States is seen in the results of their effort to establish more uniform discount rates throughout the country, in their success in harmonising commercial paper practices, in their relief of banks which would otherwise have been obliged to close on account of inability to rediscount paper, and in a variety of other less important ways. The question how far the reserve banks have succeeded in establishing a discount market or in providing a basis for financing foreign trade, both points which had been much under discussion prior to the passing of the Act, were in 1921 still matters of controversy. The provision of the Reserve Act which was intended to aid in the promotion of foreign trade authorized member banks to make bank acceptances and reserve banks to rediscount and buy such acceptances. It was natural that some time should elapse before much practical effect could be given to this provision, but it would probably have gone into operation as the result of a gradual and normal evolution had it not been for financial necessities caused by the war. In general the effect of the war was to disorganize all financial methods and systems previously in use, and this was as true in the field of commercial paper as in any other. Early in the war American foreign trade was placed upon a credit basis, and due to the difficulty of selling the obligations of belligerent Governments there was a strong temptation to obtain as much credit as possible upon a pure banking basis. The result was the lengthening of the maturity of the bankers' acceptance by every possible means and eventually the introduction of the so-called "renewal acceptance," whereby groups of banks entered into agreements which involved the making of acceptances for financing American exports to belligerents and others, at the same time that other groups agreed to buy or discount these acceptances, the first groups in return undertaking to discount acceptances made by the second group and used to take up the first issue. This was, of course, a sheer perversion of the intent of the acceptance, and when after the close of the war there developed a widespread practice of inflation and "kiting," followed eventually by an effort on the part of some accepting banks to repudiate acceptances because of the fact that heavy reductions in prices had occurred, the result was to impair confidence in American acceptances and to retard considerably the movement for their development. However so far as gross volume is concerned, the new type of paper maintained a very substantial development until 1921 when the total amount in existence was estimated by the Federal Reserve Board as approximately six hundred million dollars, but during the first half of 1921 the value declined largely. Financing of foreign trade has been on so abnormal a basis and the trade itself has been so one-sided that it would be difficult to form a conclusive estimate of the effect of reserve banking in that connexion further than to say that without the general underlying strength which had been afforded by the system it would probably have been impossible for the United States to finance any such enormous volume of trade as it actually took care of. The effect of the Reserve System

upon interest and discount rates has undoubtedly been to stabilize and harmonize them. Not only has there been a narrower variation of rates in different parts of the country than had been expected but the system has on the whole held the rates down. During the war this stability was partly due to wartime control. Subsequent to the close of the war there was a rebound to much higher rates of discount, but even these were probably by no means as high as they would have been, had it not been for the existence of the system.

*Relations to Foreign Financing (The Edge Act).*—While the original Federal Reserve Act had provided for the organization of foreign branches by qualified national banks, only a few banks showed real interest in the branch plan and only one or two took up the formation of branches on a considerable scale. Hence the adoption of an amendatory Act which authorized national banks to unite for the formation of banks which should engage in foreign trade financing. A few such banks were organized, but here also the interest of the different institutions was soon found to be limited. One reason assigned for the hesitation of banks in organizing the new corporations was the fact that they might be compelled to give to competitors an undue amount of knowledge of their own transactions. While, therefore, a few foreign trade institutions were organized, usually under the laws of New York state, with stockholders (banks) scattered throughout the country, it was evident within a year or so that this attempt to provide for the financing of foreign trade had been unsuccessful. Only in South America and the Far East (and there as a result of the provisions of the original Federal Reserve Act authorizing the creation of branches) did the banking system of the United States gain a distinct foreign development. The lack of foreign financing mechanism was obscured during the war years because of the necessity to which many foreigners were subjected of keeping their balances in New York and generally in dealing with American banks regardless of the conditions established by the law. Immediately after the close of the war modifications of this state of things began, and it became apparent that as soon as Government financing of American export trade ceased it would be impossible to maintain exportation long on anything like the basis which had existed during the war. A measure recognizing the need for an organization for export banking was taken under advisement in the winter of 1918–9 and was eventually made law in Oct. 1919. Meanwhile many American enterprises had fallen into the habit of financing their own foreign trade by extending long credits to buyers, while borrowing heavily from their own banks on domestic account in order to get the funds they needed to carry on trade elsewhere. In this way between the date of the Armistice and the close of 1920 there had been built up a foreign unfunded balance representing the difference between American exports and American imports reliably estimated as high as $4,000,000,000. One outcome of this great export balance was seen in continuous and violent disturbances of rates of foreign exchange, sterling (which had a normal par of $4.86) being depressed as low as $3.25, while other currencies suffered similarly and in some cases to a greater degree. This condition of affairs gave an impetus to the idea of establishing upon a national scale "Edge Act" corporations under the legislation already referred to, and during the winter of 1920–1 an effort was made to bring about the investment of capital in such undertakings, their purposes being to facilitate the movement of American goods to foreign countries on long-term credit.

*Conclusion.*—The Federal Reserve System between its organization at the end of 1914 and the close of the year 1921 passed through a remarkable development which not only vastly increased its resources as compared with any figures they would have been likely to reach had it not been for the war, but also necessitated active participation on the part of reserve banks in many types of financial transactions from which they might otherwise have abstained. The results of this activity were both good and bad—good in increasing the activity of the system and in affording an opportunity to be of direct and material usefulness; bad in bringing about a mushroom growth which prevented or curtailed the development of methods and practices upon a scientific basis. The system as a whole, especially those features which were at first thought to be of doubtful practicability, had definitely found its place and established its effectiveness. There had been improvement in methods of business financing, in the type of commercial papers, and in the use of modern instruments in connexion with the conduct of foreign trade. There had also been a large advance in economy, promptness and effectiveness, in domestic exchange, and in the collection of cheques. Priceless service was rendered to the U.S. Treasury during the war and through it to the world at large, since without the aid of the Federal Reserve System the financing of the war would probably have been impossible. On the other hand, the Federal Reserve System was the instrument through which an inflation of credit and prices occurred in the United States. The post-war attempt to curtail such inflation was not begun at a sufficiently early date, but was steadily working during 1921.

AUTHORITIES.—Reports of Secretary of the Treasury and of the Federal Reserve Board, 1914–20 inclusive; Federal Reserve Bulletins, 1915–20 inclusive. (H. P. W.)

**FEDERAL TRADE COMMISSION.**—This American Commission was created by Act of the U.S. Congress, approved Sept. 26 1914, for the prevention of unfair methods of competition in commerce. It is composed of five members appointed by the President, and confirmed by the Senate: not more than three members may be of the same political party. The Commission elects its own chairman. It entered upon its official duties March 16 1915. With it was merged the Bureau of Corporations, previously under the jurisdiction of the Department of Commerce.

If the Commission has reasons to believe that a "person, partnership or corporation" practises any unfair method to the prejudice of the public interest, it shall serve a notice upon such party, submit a statement of the charges, and set a date for a hearing. The party complained of has the right to appear and show cause why the Commission should not require the cessation of practices alleged to be in violation of the law. If the party refuses to obey the orders of the Commission, the Commission may apply to the U.S. Circuit Court of Appeals. Banks and common carriers are excepted, they being under other Federal supervision. The Commission is empowered to investigate from time to time "the organization, business, conduct, practices, and management" of any commercial corporation and its relation to any other corporation, and to make recommendations for a readjustment of its business alleged to be violating the anti-trust laws, including those relating to price discriminations, intercorporate stock-holdings, and interlocking directorates. The purpose of the Commission is to advise and regulate rather than to punish. It is also empowered to investigate trade conditions of foreign countries as affecting the foreign commerce of the United States, and to report to Congress with recommendations. The Commission comprises three departments: administrative; economic, in charge of investigations; and legal, for enforcing its findings.

**FEJERVARY, GEZA,** FREIHERR VON (1833–1914), Hungarian statesman and general, was born March 15 1833. He began his career in the army, and as a captain he won in 1859, for a heroic action on the hotly contested heights of San Martino in front of Solferino, the highest military decoration of the former monarchy, the cross of Maria Theresa. In 1872 he became State Secretary in the Hungarian Ministry of National Defence (Honved) and Minister of National Defence in 1884. In 1895 he persuaded the Emperor Francis Joseph to agree to the religious and political reforms of the Wekerle Ministry. In 1903 he resigned, together with the prime minister, Szell, owing to the rejection of a bill to increase the contingent of recruits, and was appointed captain of the Hungarian Life-Guards organized at that time. He was appointed premier June 18 1905. The parliamentary majority declared that the Fejervary Ministry was unconstitutional, and organized a national opposition against it. Fejervary nevertheless succeeded in settling these differences by the so-called Pactum, on the basis of which the Wekerle Ministry was formed April 8 1906. From this time onwards Fejervary's political activity ceased and he resumed his military career. On the death of Prince Esterházy, captain of the Hungarian Body-guard, Fejervary was appointed his successor. He died of cancer of the tongue April 25 1914. (E. v. W.)

**FÉLIX, LIA** (1830–1908), French actress (*see* 10.239). Her appearance in Sardou's *La Haine* in 1874 marked the end of her theatrical career. Inferior in talent to Rachel, she possessed a beauty which her more famous sister had not. She died in Paris on Jan. 15 1908.

**FENWICK, ETHEL GORDON** [MRS. BEDFORD FENWICK] (1857–), British nurse, was born at Spynie House, Morayshire, Jan. 26 1857. She was educated privately, and in 1878 entered the Children's hospital at Nottingham to be trained as a nurse. After a short time at the Royal Infirmary, Manchester, she became a sister at the London hospital (1878–81), and in 1881 was appointed matron of St. Bartholomew's hospital. In 1887 she married Dr. Bedford Fenwick (b. 1855), the well-known gynaecologist, and henceforth devoted herself largely to the work of reorganizing and raising the status of the nursing profession. From 1889 to 1896 she was managing directress of the Gordon House Home hospital, and in 1887 founded the British

Nurses' Association, of which she was the first member. Mrs. Bedford Fenwick has been a member of many medical and nursing congresses and has also contributed many papers to medical journals. She became in 1893 editor of the *British Journal of Nursing*, and was a prominent member of the Society of Women Journalists.

**FERDINAND** (1861– ), ex-King of Bulgaria (*see* 10.269), played a leading part in the negotiations which led to the Balkan Alliance and the Balkan War of 1912. It was generally believed in Bulgaria that the costly prolongation of the war in Thrace was attributable to his ambition to capture Constantinople, and that it was he who, as commander-in-chief, gave Savov the order to attack the Serbs on June 29 1913. Thus the responsibility for the disastrous second Balkan War rested with him. There is no doubt that it was Ferdinand's policy, carried out by a subservient and discredited set of ministers, which brought Bulgaria into the World War on the side of the Central Powers. He abdicated in favour of his son Boris on Oct. 4 1918 and retired to Coburg. Queen Eleanor died at Euxinograd Sept. 12 1917 (*see* BULGARIA: *History*).

**FERRIER, PAUL** (1843–1920), French dramatist (*see* 10.288), died at Nouan-le-Fuzelier Sept. 11 1920.

**FIBRES** (*see* 10.309).—Science and technical industry during the World War were necessarily impressed into war service. "Fibres," animal and vegetable, had an obvious prominence in the actual *matériel* of warfare, and their most ordinary applications assumed intensified importance. An interesting point arose in Germany and among her allies in the emergency adaptations which were devised under the stress of short supplies of staple raw materials. These restricted supplies directly influenced the production of military explosives; cotton cellulose was supplemented or replaced by wood cellulose for producing nitro-cellulose propellant explosives. The wood cellulose to be used for this purpose was prepared from the "bisulphite" pulps of the paper industry, by hydrolytic treatments under which these crude "celluloses" were purified by the removal of 10 to 15% of their weight of the less stable celluloses. The final product was characterized by a much-increased proportion of α-cellulose (Cross and Bevan), and by structural changes of the fibre; effects which may be comprehensively described as "cottonizing." This modified cellulose has been established in Germany as "Supersulfit," and for paper-making uses it has increased the range of application of wood cellulose in substituting rag celluloses. Restricted supplies of cotton, as of flax or hemp and jute, also affected the textile industries of these countries, and forced the production of twisted paper yarns to an industry of large dimensions, the estimated output in the concluding year of the war being 200,000 tons. The applications of these yarns covered a wide range of textile effects, some of which are permanently adopted. But in the main such products are substitutes, with the fundamental defect of the short fibre-length (2–3 mm.) which characterizes the better-prepared pulps of the papermaker.

These developments in any case are a permanent contribution to fibre technology, and have reopened a number of problems in the borderland region between the textile and paper-making industries, which have the common objective of producing a structure in continuous length from discontinuous elements, with the fundamental distinction of dry and wet methods. It is evident that if the control of longer fibres (*e.g.* 7–15 mm.) on the Fourdrinier machine can be realized, there would result an interesting extension of this competition of methods, in which a decisive factor would be the relative cost of production.

Another raw material to claim attention especially under the stress of war conditions was the fibre of the common nettle. The textile potentialities of the *Urticaceae* have long been recognized and the most conspicuous members of the order, which furnish the Ramie or Rhea fibre, are the basis of established industry. With their characteristics of great length of (bast) fibre they have the defects of extreme variability of dimensions, and require preparation by chemical methods of separation; from the plant, moreover, the yields of fibre on the crop-weight are low. Notwithstanding these defects, which are exaggerated in the case of the nettle, the industrial utilization of the plant has been seriously prosecuted in Austria and Germany, and it appears that, under the condition of an integral working-up of the crop material to salable products, there is a prospect of commercial development. Such treatment of the non-fibrous cellular debris of this crop-plant, as of others, after separation of the primary product—in this case the fibre—is indicated in recent developments of fermentation processes.

Still dealing with the emergency problems of the war period, the revival of the long-known effects of treating jute fibre with caustic soda (mercerizing) is noted. These effects are expressed in the descriptive term "woollenizing": the fibre is so modified as to present many points of resemblance to wool. It yields to the "carding" process, and mixes well with wools: mixtures containing up to 60% of the vegetable fibre can be worked up through the sliver and roving stages and finally spun to useful yarns. These were worked on an increasing scale in the Central European countries during the war period.

As a result of the shortage of the staple paper-making raw materials, the European industry was served in part by miscellaneous supplies of material. In England the reeds of the East Anglian rivers and other districts were brought into requisition, and experimental quantities of numerous fibrous materials were worked up into paper and boards.

The restriction in supplies of food-stuffs in Germany and Austria-Hungary brought forth a crop of substitutes (*Ersatzstoffe*). In the agricultural section attention was directed to the food value of the fibrous components of vegetable material—celluloses and ligno-celluloses—generally classed as indigestible, and cattle foods were adopted containing considerable proportions of these more resistant elements of plant structures.

The literature on this subject has more than the passing interest of the episode, and attention may be directed to the following:—"Digestibility of Birch Wood," Rubner, *Chem. Ztg.*, 1915, 39, 861; "Wood Cellulose as Fodder," Schwalbe, *Z. Angew. Chem.*, 1918, 31, 347, and Scurti and Morbelli, *Chem. Zentr.* 1919, 90, 1112, and on "Cereal Straws after various Chemical Treatments," Goddes, *Jour. Agr. Soc.* 1920, 10, 437; Fingerling, *Z. Angew. Chem.* 1918, 31, 347; Pringsheim, *ibid.* 1919, 32, 249.

These researches are obviously related to the more specific investigations of the destructive resolution of the celluloses, fibrous and cellular, to ultimate products of low molecular weight. The developments of Power Spirits Ltd. and H. Langwell have established intensive bacterial fermentations even of the resistant cellulose which have the external characteristics of the familiar operations of the brewer and distiller in the production of alcohol. Langwell's investigations have therefore brought these transformations within such control as to become industrial operations, and as the main products are alcohol and acetic acid there is the obvious economic basis for commercial development.

It is clear that such developments are only indirectly involved in the subject-matter of this article, since the fibrous celluloses and ligno-celluloses subserve as such their special adaptations to human requirements. It is possible to apply such processes to the utilization of the non-fibrous rejecta of such crop plants as flax, hemp, sisal, manila and phormium, to the production, *e.g.* of acetic acid, which would make for the economic working-up of material, and the covering of costs of production of the staple fibres yielded by these plants.

The direct contributions of these investigations to organic science are obvious and far-reaching: they extend and define certain constitutional relationships of the celluloses, as chemical individuals, of first importance; and elucidate many aspects of the plant world in its primary functions as well as its correlations of interdependence with the animal world.

The influence of war conditions likewise brought about the extension of the applications of the Kapok "fibre" (seed hair) in the composition of marine life-saving appliances. These depend primarily on the low density of a mass of this fibre, even when much compressed, as in the stuffing or filling of the familiar life-saving jackets which now replace the cork-lined appliances of the 19th century. The flotation powers of an enclosed mass of Kapok is measured in terms of the volume of unit weight (1 gramme) when forced by hand compression into a regular cylinder. This volume is 10–12 cub. cm., and is a multiple of the volume of an equal weight of cork substance of highest quality. The fibre has the further advantage of being compressible in mass whereas cork is relatively rigid. A jacket can therefore be constructed and filled with the fibre in such a way as to carry

out the ideal distribution of floating effect so as to prevent submergence of the mouth of the wearer. The properties of the fibre causing this are in the main structural. The fibre canal holds a relatively large volume of air: the smooth contour of the fibre and the resilience of the air-filled tube give a large interstitial (air) volume of the mass even under considerable compression.

In a general survey of the fibre industries there is no disturbance of their fundamental perspectives nor any radical changes in their many-sided technology to record during 1910–21. The developments of the artificial (celluloses) fibres was rather impeded under the stress of war conditions, though without prejudice to the financial prosperity of the leading manufacturing corporations. There is a new manufacture of an artificial silk from the cellulose acetate of the British Cellulose Co. (Dreyfus processes). This product, as a cellulose ester, has certain properties—*e.g.* lower specific gravity, with a water-resistant quality—which are points of superiority in relation to the cellulose "artificials." On the other hand, it is of lower tensile strength, of inferior dyeing capacity, and its cost of production is higher. Its production therefore is limited in scale.

In raw fibrous materials for the paper-making industry, there have been developments in the production of cotton-seed lint, and the preparation of pulp from the bamboo, and of a concentrated fibre (quarter-stuff) from the papyrus (*Cyperus*). (See E. de Segundo, "Residual Fibres from Cotton Seed," *Jour. R. Soc. Arts*, Feb. 1919; C. F. Cross, "Cellulose Industries," *ibid.* 1920 [Cantor Lectures]; W. Raitt, "Paper Supplies from India," *ibid.* May 1921.)

Note should be made of an investigation by W. L. Balls of the ultimate structure of the cotton fibre. By a chemical reaction which induces a controlled distention (by hydration) of the cell wall, without structural distention, the dimensions of the structure are exaggerated to a large multiple which brings into evidence a series of concentric rings which are the daily growth rings of the hair or fibre (*Proc. R. S.*, B., vol. xc. 1919). (C. F. C.)

**FILON, (PIERRE MARIE) AUGUSTIN** (1841–1916), French man of letters (*see* 10.345), died at Croydon May 13 1916. In 1910 he published a short biography of *Marie Stuart*, and in 1911 *L'Angleterre d'Edouard VII.* and a dramatic poem *Shakespeare amoureux*. His *Souvenirs et documents*, relating to his former pupil, the Prince Impérial, appeared in 1914.

**FILTER-PASSING GERMS.**—The discovery by Pasteur of the significance of microbic life in the phenomena of fermentation, putrefaction and disease and the development by Koch of an appropriate technique for the new science of bacteriology had already led in a comparatively few years to the determination of the causation of many infectious diseases of man and animals. There remained, however, a number of diseases of man and animals—and amongst these some common maladies such as typhus, measles, smallpox, foot and mouth disease, swine fever, rabies and cattle plague—in which the cause had not been discoverable by the methods of microscopical examination and cultivation which proved successful in so many cases. It was suggested by Pasteur, who searched in vain for the infective agent of rabies, that some microbes were too small to be visible with the optical apparatus at disposal. There is no reason *a priori* to suppose that the lower limit of size of microbic organisms should be of a dimension at present discernible, and the question raised by Pasteur was answered ten years later by the discovery made by Loeffler in 1898 that the virus of foot and mouth disease was invisible. The limit of visibility of a particle is in the last instance conditioned by the wave length of light. With the best modern microscopes employing white light of which the average wave length is $0{\cdot}55\mu$ ($\mu = \frac{1}{1000}$ mm.) this limit is rather less than $0{\cdot}2\mu$. If ultra-violet light of half this wave length is used, photographs of objects of about $0{\cdot}1\mu$ in diameter can be made. The existence of particles of much smaller size can be demonstrated by the method of dark-ground illumination (Tyndall phenomenon), when they appear as bright points. The limit appears to depend upon the intensity of illumination and with direct sunlight is $0{\cdot}004\mu$.

Invisibility of a microbe commonly handicaps every effort at its isolation, propagation and identification, but does not render them impossible of achievement, for the existence of a living virus in an optically clear liquid may still be demonstrated by its power to infect an animal or plant, or produce recognizable chemical changes in a medium. The existence of these ultra-microscopic viruses was brought to light unexpectedly through the instrumentality of so-called "bacterial filters." These are constructed of fine-grained unglazed porcelain, clay or infusorial earth. They are commonly moulded in the shape of hollow candles and fired at a high temperature. Liquid is made to pass through the walls of the filters, which vary from a quarter to half an inch in thickness, by hydrostatic pressure or by suction with some form of exhaust pump. Use of such filters to separate bacteria from the products of their activity was first made in 1871. Since that time they have become a usual part of the equipment of a bacteriological laboratory and have been extensively employed to free water from microbes for domestic use. In structure the wall of a filter resembles a bed of sand on a diminutive scale, with crevices of variable size between the particles and a good many splits and holes of larger dimensions throughout the matrix. The different types of filter vary in their permeability according to the fineness of the pores and thickness of the wall. The smallest passages are of the order of $0{\cdot}2$ to $0{\cdot}5$ in the case of the porcelain filters and $0{\cdot}2$ to $0{\cdot}8$ in those made of infusorial earth. The size of the smaller pores is of the same order of magnitude as that of the smallest bacteria, and the power of a filter to hold back these microbes depends upon the walls being of sufficient thickness to ensure that a bacterium will become impacted in one of the smaller passages through which the liquid in which it is suspended has to pass. If a filter through which a liquid containing bacteria in suspension has been filtered be allowed to remain for a few days immersed in a nutrient fluid, the bacteria caught in the interstices divide and multiply and generally manage to grow through the walls of the filter, for, during growth, the cells can adapt themselves to the size and shape of the crevices. On this account filters cannot be relied upon to render drinking-water secure unless removed and sterilized by heat at least every second day. The similarity in magnitude of filter-pore and bacterium is not a coincidence, but due to selection of material for the manufacture of the filters of such size of grain as to afford a bacteria-free filtrate and at the same time the maximal flow of liquid. In other words, bacterial filters have been made to fit the known microbes.

The first discovery of an ultra-microscopic or filterable virus was made by Loeffler in 1898 in the course of some experiments upon foot and mouth disease in which a filter of infusorial earth was being used to remove ordinary recognizable bacteria from the diluted contents of the superficial vesicles which are characteristic of this disease. The filtrate was free from any particles visible by the microscope and no bacteria developed in it on cultivation. Nevertheless, injection of this filtrate into animals caused the disease. Material removed from the vesicles of the animal so infected and filtered again reproduced the disease in a fresh animal. Similar experiments were carried out through a number of generations of experimental animals, so that there was no doubt that a virus capable of propagation was contained in the filtrates. In the next few years the filterability of the virus was established in the case of infectious pleuro-pneumonia of cattle, South African horse-sickness, fowl plague and mosaic disease of the tobacco plant, in which patches of discoloration occur in the leaves and, spreading rapidly, destroy them. With the exception of the virus of pleuro-pneumonia, which is just on the margin of visibility, all are invisible.

The first virus of a human disease which was found to be small enough to pass a bacterial filter was that of yellow fever. The observation was made by the American commission to study yellow fever in Havana in 1901. The cause of yellow fever has recently been shown to be an organism which, owing to its thinness and motility, can pass through a bacterial filter.

Up to the year 1921 the virus of 38 diseases of man, animals or plants had been found to pass through a bacterial filter by some reliable observer. The more important of these are the following: foot and mouth disease, contagious bovine pleuro-pneumonia, mosaic or spotted disease of the tobacco plant, African horse-sickness, fowl plague, yellow fever, cattle plague,

sheep-pox, *epithelioma contagiosum* of birds, swine fever, rabies, cow-pox (vaccinia), *molluscum contagiosum* of man, equine infectious pernicious anaemia, canine distemper, "blue tongue" of sheep, dengue fever, papataci or sand-fly fever, smallpox, trachoma, poliomyelitis, scarlatina, measles, typhus fever, and trench fever. There are many observations indicating that the primary cause of pandemic influenza may be a filterable virus.

Two filterable viruses fall into a class apart. They are distinguished from the others in that they do not seem to produce disease directly by their poisonous activities but rather to stimulate certain cells of the body in the neighbourhood of their inoculation to excessive and anarchical development. The injection of these viruses into certain varieties of fowls leads to sarcomatous new-growths of great malignity. In the one case it is a pure sarcoma, in the other a mixed tumour, an osteo-chondro sarcoma. These malignant tumours spread not only by proliferation at the point of origin but some of the cells of which they are composed, boring their way into blood vessels and lymphatics, are carried all over the body, giving rise to similar tumours in internal organs. The metastases as well as the primary tumours contain the virus, and if extracted with water and filtered through a bacterial filter, whereby all the cells of which the tumour is composed are held back, the filtrate may be dried and powdered and the powder retains its original property of exciting the formation of these malignant tumours in suitable animals into which it is injected. The experiment may be repeated indefinitely through generations of young chicks, showing that the virus propagates itself and appears to live in some sort of symbiotic manner with the particular cells it excites to inordinate development.

It frequently happens that one observer succeeds in passing a particular virus through a filter, whilst another fails. When the particles of a virus are of the same order of magnitude as the crevices of the filter this may well happen, as in any case the majority will be retained in the wall of the filter. Even when the size of the particles of virus are much less than that of the smaller pores, they are liable to be deposited upon the walls of the minute passages under the influence of surface action and the filtrate becomes thereby greatly reduced in concentration.

In addition to size, shape, and rigidity of particles, the conditions under which filtration is carried out, pressure, temperature and amount of liquid passed through the filter, exert an influence. With high pressure some may be forced through which would otherwise be obstructed. This is particularly the case when the particles are of unequal dimensions in two planes. The nature and reaction of the liquid in which the virus is suspended is also of importance. If suspended in a colloidal solution such as blood serum or a slimy emulsion of nerve tissue, high dilution is necessary for the colloidal particles of the solution or emulsion are themselves deposited on the walls of the pores and rapidly reduce the permeability of the filter. Reaction plays a part by modifying the electric charge on the particles and thereby facilitating or hindering their aggregation and deposition on the surface of the filter pores which is also charged.

The fact that a virus, under certain circumstances, traverses a bacterial filter, does not tell us any more as to its nature than that it is very small, or at least very thin, and of the order of 0·1 to 0·2 $\mu$ or less in its smallest diameter. It is not necessary to assume a *contagium fluidum* in the case of those viruses which are outside the range of visibility under the best optical arrangements at present available. The particulate nature of the infective agent of rabies, fowl plague, variola and vaccinia, is indicated by the fact that the upper layer of a liquid containing them may be deprived of infectivity by prolonged subjection to a powerful centrifugal force.

Little is known about most of these filterable viruses. They appear to be of various natures, and the only property common to them is minuteness. The parasite responsible for yellow fever is a small spirochaete, those occasioning bovine pleuro-pneumonia and human poliomyelitis are just on the margin of visibility and have been cultivated in artificial media. Some of them occur in the blood of the patient during the acute stage of the illness and are transported to a fresh host by the bite of blood-sucking insects. The infections of yellow fever and dengue are conveyed by the mosquito (*Stegomyia fasciata*). That of papataci fever is transmitted by the sandfly (*Phlebotomus papatasii*), and that of typhus and trench fevers by lice. In each case some days elapse before the insect is capable of handing on the infection, indicating that an interval for the multiplication of the parasite is necessary. It is possible that a stage in the life-history of the parasite can only occur in the body of the insect host. Some filterable viruses, such as smallpox, cowpox, foot-and-mouth disease, and *molluscum contagiosum* give rise to superficial lesions, and are spread by contact; others occasion catarrh of the respiratory passages and are distributed by coughing and intimate contact, as in distemper, measles, scarlet fever and pleuro-pneumonia. In many cases the precise method of infection had still been undetermined in 1921.

(C. J. M.*)

**FINANCE** (*see* 10.34).—The continuous developments of national finance in the different countries of the world during 1910-21 are dealt with in articles under separate headings, where the relevant statistics in each case will be found (*see* ENGLISH FINANCE, and the sections on "finance" in the articles under country-headings, *e.g.* UNITED STATES, FRANCE, GERMANY, etc.). Under other headings also the mechanism of finance and the chief subjects of general financial-economic interest are further discussed, historically and statistically, on their own account. Thus the new developments of special moment arising in connexion with the market for securities are discussed under STOCK EXCHANGE, those affecting the money-market under MONEY-MARKET, questions of foreign exchange under EXCHANGES, FOREIGN, banking under BANKING (together with the article on the new FEDERAL RESERVE BANKING SYSTEM in the United States), and insurance in its various forms under INSURANCE. Similarly, reference may be made to the articles NATIONAL DEBT, GOLD, SILVER, WAR LOAN PUBLICITY CAMPAIGNS (British), LIBERTY LOAN PUBLICITY CAMPAIGNS (American), DOLLAR SECURITIES MOBILIZATION (as part of British Government finance during the war), SAVINGS MOVEMENT, INFLATION, PROFITEERING, INCOME-TAX, EXCESS PROFITS DUTY, COST OF LIVING, WAGES, PRICES, FOOD SUPPLY, RATIONING, CAPITALISM, COMMUNISM, MARKETING, etc., for particular questions which have either loomed larger, or emerged as practically new problems, in the financial and commercial world. Incidentally, the financial effects of the World War form an integral part of the history of every form of human activity during the period, and therefore receive appropriate consideration under numerous other headings where the subject-matter belongs to the sphere of business and economics.

It only remains here to gather up the threads of the general world-situation in finance, as it stood towards the close of 1921.

The end of the war had left the whole financial world in 1919 in a state of chaos.[1] Its conditions were comprehensively reviewed in 1920 at the International Financial Conference which, as arranged by the League of Nations in Feb., met at Brussels from Sept. 24 to Oct. 8. There were 86 representatives of

[1] Nothing is said here of Russia, which, economically and financially, was in collapse, with its internal and external trade-relations completely paralyzed (*see* RUSSIA). It may be mentioned that, in 1921, a somewhat farcical turn was given to the hopeless depreciation of the ruble by an official exchange-rate of 133,000 rubles to the £ being "fixed" by the Soviet government. Any other huge figure would have done as well! The progress of ruble inflation is shown by the following figures for the total issues in circulation (in million rubles):—Aug. 1914, 1,709; Jan. 1915, 3,215; Jan. 1916, 5,737; Jan. 1917, 9,225; Nov. 1917 (Kerensky), 18,917; Jan. 1919 (Bolshevist), 61,265; Jan. 1920, 225,216; Jan. 1921, 1,168,598; Jan. 1922 (est.), 2,000,000.

[2] Pre-war figures in dollars at par of exchange: post-war at exchange of Sept. 30 1920. [3] Reparations liability excluded.

39 countries at the conference—Argentina, Armenia, Australia, Austria, Belgium, Brazil, Bulgaria, Canada, China, Czecho-slovakia, Denmark, Esthonia, Finland, France, Germany, Greece, Guatemala, Holland, Hungary, India, Italy, Japan, Latvia, Lithuania, Luxemburg, New Zealand, Norway, Peru, Poland, Portugal, Rumania, the Serb-Croat-Slovene State (Yugoslavia), South Africa, Spain, Sweden, Switzerland, United Kingdom, United States, and Uruguay.

In the Final Report of the Conference (as adopted on Oct. 8), it was pointed out that the effects of the World War had varied immensely according as the various nations had been involved in it. Among the European belligerents, Belgium, Bulgaria, France, Germany, Great Britain, Greece, Italy and Portugal, had become burdened with an enormous volume of debt, internal and external. Their internal debt (converted into American dollars at par) had reached about 155 milliards (thousands of millions of dollars) as compared with about 17 milliards in 1913; and their new external debt was about 13 milliards. Their expenditures had increased by amounts varying between 500 and 1,500 per cent, reaching between 20 and 40 per cent of their national incomes, the highest percentage being shown by France. In spite of attempts to restore their financial equilibrium, in some instances by the imposition of additional taxation, they still showed (with the exception of Great Britain) a large gap between income and expenditure.

They had lost a large proportion of their pre-war gold-holdings and had enormously increased their paper currencies. A number of new states had been created as the result of the war, while some previously existing states had had their territories profoundly modified. These included Armenia, Austria, Czecho-slovakia, Esthonia, Finland, Germany, Hungary, Latvia, Lithuania, Poland, Rumania, Serbia and Turkey. In most of them the machinery of an orderly financial system was not yet in operation in 1920.

[1] Gold in banks only. [2] Includes gold in circulation.

In the neutral European countries, including Denmark, Holland, Luxemburg, Norway, Spain, Sweden and Switzerland, financial difficulties were also serious. Heavy expenditure had been incurred owing to the war, and they had had largely to increase their internal debts. This increase in expenditure was mainly due to rise of prices. In some cases it had been met by increased taxation, but Holland, Switzerland and Spain showed considerable budget deficits. During the war their trade balances had been made artificially favourable, owing to demand by the belligerents for their products, and the stoppage of imports; and the resulting accumulation of gold in their banks had led to expansion of currency and a further rise in prices. After the war they had to import goods to replenish stocks, and, owing to the premium on their exchanges as compared with the depreciated currencies of the belligerents, it was difficult to maintain their export trade; thus what would otherwise have seemed favourable factors had become an embarrassment.

It was the countries outside Europe that were most favourably situated economically. Some of them had been able to pay off a large part of their external debts and had even made loans to former creditors. This was particularly the case with the United States of America. But there, too, the accumulations of gold had helped the rise in prices, and the appreciation of exchange rendered more difficult a maintenance of exports, for which the restoration of purchasing power among their European customers was necessary.

In every country of the world, the purchasing power of the national currency had diminished; and the cost of living, as

expressed in terms of that currency, had increased. With few exceptions, neutrals as well as belligerents (the United States standing alone in this respect) had ceased to be on a gold basis, and in any case the value of gold itself in terms of commodities had diminished to about one-half. International trade had been dislocated, and diverted from its normal channels. The inability of Europe to export during the war had forced normal customers to look elsewhere, and to develop production at home or in new centres overseas; and Europe's need for imports had compelled realization of her foreign capital holdings, which were thus no longer available as a credit basis. Instability and depreciation of exchange impeded both buyer and seller. With half the world producing less than it consumed and having insufficient exports to pay for its imports, credits alone could bridge the gulf between seller and buyer, and credits were rendered difficult by the very causes which made them necessary.

[1] Includes notes of National Bank of Rumania and notes issued during the German occupation; excludes kroner, ruble notes, etc. [2] March 1920. [3] February 1920.

Such being described as the position in 1920, the Conference came to its recommendations. And the Report premised that, first and foremost, what the world still needed was peace. "Finance" was, after all, only a reflection of commercial and economic life; as the wealth of the world consists of the products of man's work, the sum total of human prosperity could only be increased by an increase of Production; and all that organized international action could provide would be conditions favourable to Production, the most important of which lay outside the financial sphere. Social content, and the "will to work," must first be restored. Yet, even if a maximum Production were to be attained, it still required a financial system which would facilitate exchange and distribution, and herein lay the problems which the Conference had met to consider. The financial statements presented by the various countries showed that, on the average, about 20 per cent of national expenditures was still being devoted to armaments, and the Conference affirmed that "the world cannot afford this expenditure." There must be an agreement to reduce it. In nearly three out of four of the countries represented, and in nearly 11 out of 22 of European countries, budgets in 1919–20 did not balance, and many of them showed no prospect of doing so in the near future. Where national expenditure was higher than existing revenue, fresh taxation must be imposed. Government subsidies, concealing the real cost price of commodities, must be abandoned. Loans required for urgent capital purposes must be raised out of the real savings of the people; and since these savings had so largely been pledged ahead for past war-credits, the first step must be to fund undigested floating debts. Currency inflation (which had substantially represented undertaxation or the existence of an unscientific system of taxation) must be stopped, and it was desirable to take any possible steps towards the restoration of an effective gold standard; but deflation must be carried out gradually and with great caution, and the Conference regarded it as useless to attempt to fix the ratio of existing fiduciary currencies to their normal gold value, nor would it recommend any scheme of "stabilization" for the value of gold, believing that neither an international currency nor an international unit of account would serve any useful purpose. Attempts to limit fluctuations in exchange by artificial control on exchange operations were futile and mischievous; but in countries where there was no central bank of issue one should be established; and if the assistance of foreign capital were required for its promotion some form of international control might be necessary.

The Conference recognized that time would be needed for financial reconstruction, and some countries could not resume economic activity without foreign assistance; but a warning was given generally that external credits should not be accorded directly by foreign Governments. It was suggested that an international organization should be formed for arranging credits for states which needed the means of paying for essential imports, and such states would have to notify what assets they were prepared to pledge as security; bonds issued against such a state guarantee might be used as collateral for credits intended to cover the cost of commodities (the Ter Meulen plan: *see* EXCHANGES, FOREIGN). Meanwhile, international commerce should, as soon as possible, be freed from artificial impediments.

Finally, the Conference drew the attention of the League of Nations to the advisability of providing various miscellaneous reforms,—unification of laws relating to bills of exchange and bills of lading, reciprocal treatment of branches of foreign banks in different countries, publication of financial information in a clear comparative form, an international clearing-house, and other such matters; and an international understanding was also advocated under which, while effective systems of taxation

should be adopted in each country so as to ensure full contribution from individuals according to their capacity to pay, there should be avoided any such incidence of "double" taxation which would form an obstacle, as it was still doing, to the investment of capital abroad.

Among the documents presented to the Conference (and published with the Report) there was included a large amount of material of permanent value to the financial historian, the nature of which can only be indicated here—statements of the existing financial position in each country, together with analyses of international trade movements, gold holdings and currency expansion, and papers by financial experts on the main outstanding problems. Taken as a whole, these documents provided a full comparative account of the changes in the international financial position between 1913 and 1920.

In the separate articles on national finance in this Encyclopaedia, under the headings for each country, its history during the extended period of 1910–21 is sufficiently narrated to make it unnecessary here, however, to refer to anything but general and comparative international considerations; and for the purpose of showing the salient changes between the pre-war and post-war positions the most instructive figures presented to the Brussels Conference (comparison being best shown in terms of dollars) are probably those reproduced in the accompanying tables (partly rearranged), representing national wealth (income) as compared with budget revenue and expenditure (Table I.), national taxation in 1920 (Table II.), the burden of debt (Table III.: *see* also NATIONAL DEBT), gold-movements between 1913 and 1919 (Table IV.), notes in circulation (Table V.), and the amount of foreign trade (Tables VI. and VII.). For the foreign-exchange problem, *see* EXCHANGES, FOREIGN; but here the comparative figures are brought up to the latest available dates in the two tables (VIII. and IX.) which show the London rates on Dec. 22 1921, and the New York rates on Jan. 14 1922.

In spite of the recommendations of the Brussels Conference, very slight progress was made during 1921 so far as the general position of international finance was concerned. The depression in trade, affecting more particularly the United Kingdom and the United States—the only countries intrinsically capable of functioning up to their productive capacity—consequent on the lack of international purchasing-power, and really representing a world-condition of underconsumption (mistakenly called "overproduction" by those who looked only at its superficial aspect), added to the difficulties of immediate recovery. The protracted controversies in the political arena over reparation-payments by Germany, due partly to aggressive French insistence, partly to a general lack of comprehension of their economic aspects, left European statesmen little opportunity to devote themselves to ordinary business questions. The instability of the exchanges made the situation peculiarly difficult for the business men themselves. The fact that the United States, during 1920–1, had disinterested itself in European troubles, and was not lending the financial assistance and coöperation which had been so confidently expected when the war ended, was a vital factor in the financial *détente*. British Labour was in serious conflict with Capital and with the Government; and the troubles in Ireland, together with the public demand for more drastic Government economies in expenditure ("anti-waste"), made it impracticable for Great Britain to take the lead in securing any material advance towards a constructive world-policy in international finance. A theoretically correct, but practically premature, policy of "deflation," on the part of the official pundits in London, together with the crippling effect of the very high scale of taxation, kept British Government finance technically "sound," but it checked British industrial and commercial enterprise at a stage when wiser counsels, if they could have been brought into operation, should, it may be thought, have put into the forefront the provision of financial facilities for the rebuilding of British trade. And in the United States the same policy, adopted by the American bankers and Government from the lead given by the Bank of England and in Whitehall, was followed, as in Great Britain, by a great increase of unemployment, although, merely from a financial point of view, it might have seemed that American resources should now have been ample—by contrast with British—for a more "adventurous" programme. In the financial history of 1919–21 no fact, indeed, is likely to seem more remarkable eventually than that, during this period, the United States, which had been unhurt by the war and had made enormous profits during the course of it—which had been converted from a debtor into a creditor country,

and had been the recipient of such huge amounts of gold from Europe—should, in its banking operations, have only hoarded this gold, without utilizing it as a further basis of interest-producing credit, up to the point of accumulating a domestic banking reserve of about 75 per cent, at a time when the whole of the rest of the world was in want of capital to set business going again. The American people were slow to see that the appreciation of the dollar was a source of weakness, not of strength.

On Jan. 1 1922, according to the U.S. Treasury Department's annual Report, the stock of gold (which had reached the highest point yet known), the amount of Federal Reserve notes, and the total stock of money, in the United States, showed the following figures (in dollars) as compared with the corresponding figures on Jan. 1 in the preceding years back to 1915:—

| Jan. 1 | Gold $ | F.R. Notes $ | Total Money $ |
|---|---|---|---|
| 1922 | 3,656,988,551 | 2,781,791,260 | 8,282,433,487 |
| 1921 | 2,784,834,427 | 3,735,719,345 | 8,372,959,004 |
| 1920 | 2,787,714,306 | 3,295,789,145 | 7,961,320,139 |
| 1919 | 3,080,510,011 | 2,559,843,920 | 7,780,793,606 |
| 1918 | 3,040,439,343 | 1,350,764,025 | 6,256,198,271 |
| 1917 | 2,864,841,650 | 300,106,180 | 5,012,045,517 |
| 1916 | 2,312,444,489 | 214,125,000 | 4,401,988,337 |
| 1915 | 1,815,976,319 | 17,199,225 | 3,972,373,686 |

In spite of this apparent evidence of monetary wealth in the United States, trade had languished there during 1920 and 1921, and complaints of overtaxation were as rife as in England. American public opinion had not yet realized the interdependence of international finance in its bearing on national economic prosperity, nor had any general appreciation of the full meaning of the expositions of financial doctrine given at the Brussels Conference penetrated to the hearts of the business community. It still remained for the world's statesmen to put their heads seriously together in a coöperative effort to restore world-consumption, through a revival of world-purchasing-power, to the level of world-productive-power, the first essentials being peace, reductions in State expenditure, and a new progress in private savings for capital investment.

It was not till the Washington Conference, at the end of 1921, that the United States once more came into practical touch, officially, with the European situation; and even then its scope did not include the great international financial problems still awaiting attention. At the opening of 1922, however, the prospect was held out of another general financial conference, as proposed by the Italian Government to be held at Genoa in March; and it seemed likely in various other directions that, during the year, an improvement might be seen in the functioning of world-finance.

(H. Cr.)

**FINLAND** (*see* 10.383).—The remarkable development of Finnish nationalism in the closing decades of the 19th century was primarily directed against the Swedish language and Finno-Swedish cultural domination. Through the revival of their own singularly rich and beautiful tongue, the Finns of Finland had learnt to think of their country as "Suomi," as utterly distinct from Sweden and Russia, as possessing thought and literature of its own. Though open to European influences, specially in their art, and taking their political ideas from Scandinavia and Germany, the "Fennomans" (Finnish Finns) climbed "unto a language island" and, developing along extremely democratic lines, took no part at all in Russian affairs and showed little interest in those of Scandinavia. There was no sympathy even with the Russian proletariat in its early struggles, while the revolutionaries were cold-shouldered.

*Second Period of Russification 1908–14.*—The successive governors of Russia, however, regarded the "Suomilaiset" (or the people of the fens) as a strange and totally different nationality from themselves, although the Finno-Ugrian race blended with the Slav is to be found all over northern Russia; they could not forget that the "country of the thousand lakes" had been under Swedish rule for 600 years, and cherished a civilization wholly alien to their own. This so obviously democratic, almost self-governing grand duchy of Finland was a thorn in the side of the vast autocratic Russian State conception. Out of this train of thought arose Russia's first attack upon the liberties of Finland during the dark years 1899–1906.

This article does not deal with the first attempt at Russification when the Finnish constitution was suspended and the country came under the rule of the military dictator, Gen. Bobrikov. This earlier period of repression was arrested by the Russian Revolution of 1905 which, in the wake of the disasters of the war against Japan, forced a weakened Tsardom to concessions. The manifesto of the Emperor-Grand Duke of Nov. 4 (Oct. 22) 1905 annulled all unconstitutional interferences of the preceding seven years and enabled the dominant Finnish Constitutional party to democratise the Diet on the broadest basis—full adult suffrage, regardless of property, class or sex, coupled with proportional representation based on d'Hondt's distributive principle which contains safeguards against the tyranny of the majority. That was gain. But the Russia of post-revolution days was still the landlocked colossus whom Panslav aspirations directed against all that was alien in language, religion, character and administration. What had led to conflict with the Tsar now led to conflict with the imperial Duma—the tendency to create one vast homogeneous Russia stretching from the Norwegian coast to the Pacific. In this scheme of power, the first step towards the ultimate possession of the warm-water ports of Scandinavia was, once again, the Russification of Finland.

The initial cause of friction was, as on previous occasions, the question of the payments to Russia in lieu of military service. The Diets had voted an annual indemnity of 10 million Finnish marks in respect of the years 1905–8, though reluctantly, not only on account of the financial burden the people were called upon to shoulder, but by reason of the unconstitutional argumentations upon which the demands were based. More particularly, the first one-chamber Diet which passed the grants in respect of the years 1907 and 1908 expressed the hope that this matter be either thereby considered regulated or else settled forthwith in a constitutional manner. This notwithstanding an imperial ukase, dated Oct. 7 1909, declared the issue to lie solely within the competence of the Crown, and peremptorily fixed an annual contribution which, beginning at 10 million Finnish marks, was to increase automatically by a million a year until, in 1919, it was to attain its maximum total of 20 millions of Finnish marks. The objections of the Diet, which was even now ready to compromise, were answered by its dissolution and the annual amounts due made over to the Russian exchequer. The same occurred with the new Diet in March 1910 in respect of the contributions for the years 1910 and 1911. Finally the Duma, by the imperial law of Jan. 23 (10th) 1912, approved of the principle of the Finnish annual indemnity in lieu of military service.

The interference of the Tsar with the constitutional rights of Finland was provocative and for that reason opened the new era of conflict. From the spring of 1907 to the spring of 1909 had supervened the two "crowded years of glorious life," of great internal progress and political development. The old feuds of "Svecksman" (Swedo-Finn) and "Fennoman" (Finno-Finn) had been taken up with renewed vigour. Aristocracy, middle class and proletariat were all politically equal; capital and labour, though frequently in conflict, yet fought their battle more scientifically than anywhere else in Europe. But by the end of 1909, the fresh wave of Russification

paralysed all recent progress. The large measures of domestic reform passed by the Diet, and generally accepted by the Senate, were laid before the Tsar and never heard of afterwards. Such was the fate of the bill for the total prohibition of alcohol, as of measures relating to the care of children, insurance, old-age pensions, education, public health and the betterment of the condition of the "torpare" (landless worker upon the soil). Civil marriages, however, were instituted, illegitimate children placed upon a better basis, and the principle of "equal pay for equal work" was applied in teaching, in the printing trade and, in 1913, in the State service.

As early as June 2 (May 20) 1908 an imperial instruction had dealt with the regulation of Finnish affairs which affected the interests of the Russian Empire as a whole. It provided that the measures passed by the Diet and sanctioned by the Senate were no longer to be conveyed to the Tsar through the Secretary for Finland, but in order to obtain the imperial assent had to come before the Council of Ministers. To stifle opposition, the imperial ukase of March 27 (14th) 1910 laid down that the question as to whether Finnish affairs affected the interests of the Russian Empire or not rested not with the Finnish Diet, but with the imperial Duma. The new law came into force on June 30 (17th) 1910 after having been passed by the Duma amid triumphant shouts of "Finis Finlandiae."

This, "The Imperial Legislation Act," taken as a whole, never came into working since in the last resort it meant the complete unification of the grand duchy of Finland with Russia in language, education, finance, customs, laws, monetary system, press restriction, rights of assembly, etc. But inconsequently applied though it was, it roused great indignation not only in Finland, but throughout Europe. The claim of this bill, which was that the assurances given by the Tsars depended upon their autocratic rule and became null when they delegated some of their governing power to the Duma, called forth protests from members of the British, German, French, Italian, Dutch and Belgian Parliaments.

Directly the "Imperial Legislation Act" had come into force, two imperial laws were laid before the Diet which, however, refused them both and was promptly dissolved. The bills thereupon came before the imperial Duma, which passed them rapidly. One of these was the law of Jan. 23 (10th) 1912, already referred to above, in which the Duma affirmed the principle of an annual Finnish indemnity in lieu of military service, while the other, of Jan. 20 (7th) 1912, accorded full citizen rights to temporary Russian residents in Finland. This last-named measure, apart from its manifest injustice, led to great confusion in the overlapping of two fundamentally different codes of law, but the judges who resigned, rather than be a party to it, were deprived of their pension rights. Every single provisional governor was forced to leave the service or did so voluntarily; many high officials suffered imprisonment or exile. The government of the country was carried on by a packed Senate, in which after 1912 sat not only pliable Finns but Russian-born members; the Diet was capriciously summoned and dismissed, the press censored. Thus the conflict with the Duma in the years 1910–4 led to sufferings analogous to those in the struggle against the high-handedness of the Tsar in 1899–1906.

In addition, it should be mentioned that Finnish propaganda abroad met with less success on this occasion, for one thing because it was a twice-told tale, for another because England had, by the logic of European events, been drawn towards Russia politically.

*Effects of the World War, 1914–8.*—In these circumstances supervened the World War of 1914, and it was left to Lt.-Gen. F. Seyn, the governor-general, to supervise the stringent censorship and the harassing restrictions of personal liberty which an unprecedented situation called for in all the countries of Europe. Though Finland escaped the horrors of foreign war upon its own soil, a descent of the German armies upon the coast was a military eventuality which had to be taken into account. Accordingly two lines of trench covering the chief railway lines were constructed across Finland, one system of fortified lines running from Tornea to Helsingfors, the other from Kajana to Kotka. Besides, the long sea border of the grand duchy was exposed to enemy action from the sea; and some 40,000 tons of the Finnish mercantile marine, which sailed under the Russian flag, exposed to destruction in the open waters of the Baltic Sea, remained locked in the harbours of the Bothnian gulf. This heavy loss to seaborne commerce was balanced by the extraordinary advantages which Finnish industries derived from the war partly by reason of the low tariff prevailing, partly through the influx of Russian labour. Industries connected directly with military supply, as also the iron, leather, glass, drugs and polishes trades and paper-manufacturing concerns, attained unexampled prosperity. The Russians, who were well aware that the Finnish people at the end of a 15 years' constitutional struggle did not love them, strongly garrisoned the country, but, the discipline in the Tsarist armies being maintained at a high standard, collisions between the military and the civil population were few. The Russian authorities, impulsive as was their wont and inconsequent in their application of the law, suffered from divided councils, and were alternately bent on reconciliation and repression. There being no means as in Sweden and Denmark to take advantage of leaks in the Allied blockade, the price of living gradually rose, railway fares and telephone costs being raised by 25%. But the country was relieved of the burden of the annual military indemnity, and the Russians, in their sporadic anxiety to please, were strangely negligent of such essential precautions as the surveillance of telephonic communications. There was, however, a special 5% tax on property and mortgage.

The course of the war, which during the first two years carried the Austro-German invading hosts through Poland and Lithuania to the confines of Great Russia proper by the marshes of the Pripet, was followed by the Finns with the anxiety of a people whose hope lay in a Russia which, weakened by a colossal military effort, would again be willing to respect the legal rights of the grand duchy. The Polish manifesto of the Grand Duke Nicholas was held to leave the Russian Government with a programme aiming at the final destruction of Finnish autonomy and nationality. Under the circumstances sympathy for the sufferings of Belgium was obscured by the consideration that France and England were the allies of that Russia which, if she emerged victorious, would again turn oppressor. In 1915 a Finn set fire to the Allied stores at Archangel in service, as he considered, to his Finland, where, as is now known on the authority of M. Sario who became Foreign Secretary of the White Government in 1918, persons were not wanting who referred to German victories as "our victories." Only some 2,000 Finns volunteered for the Russian army, where, however, they fought with traditional valour under their own officers. About the same number enlisted in the German army, though ostensibly only for service on the eastern front, and did not return until the *coup d'état.*

Towards the close of 1916 the magnitude of the industrial effort in neglect of agricultural development was fast bringing its own punishment. Finland had changed—as far as her size, climate and scanty population allowed—from an agricultural to an industrial country in two and a half years. The ruin of her dairy trade drew workers into the factories, and, an ever more considerable part of Russian war material manufacture passing into Finnish hands, labour streamed in from the country and from across the Russian border. Wages rose with the increasing cost of food, and great fortunes were made while there was yet considerable unemployment. This happened in a country which even normally produced but five-sixths of her needful foodstuffs, at a time of world shortage and under pressure of an ever more effective blockade; in one, too, which, while the old order survived in Russia, was debarred from any sort of political expression. True, elections were still held in 1916, and resulted in the return of a Social Democratic majority, but the Diet was not allowed to function.

*The Russian Revolution, March–Nov. 1917.*—Then came the Russian Revolution. The Tsar Nicholas II. Alexandrovich abdicated on March 15 1917 and the new Provisional Government of Russia almost with its first breath restored representative government in Finland. The Russianized Senate was dissolved and a temporary body of twelve, half of whom were Social Democrats and the remainder members of the bourgeois parties, took up the executive power. Gov.-Gen. Seyn was replaced by Stakovich, while Rodichev, a tried friend, became Secretary of State for Finland. Kerensky, visiting Helsingfors at the end of the month, placed a wreath at the foot of the statue of Rüneberg, the national poet, and uncovered his head when the Finnish national anthem was intoned. The former Socialist speaker of the Diet, M. Tokoi, was nominated president of the Senate; Kullervo Manner, a young Finnish Social Democrat, was made speaker of the Diet; Vaino Jokinen, his former collaborator on the workman's journal "Tyomies," and Lauri Ingman, a clergyman and a Swede of the Swedish party, became vice-speakers.

It was then quite clear that ever since 1907 the one constant factor in Finnish political life had been the growth of the Social Democratic vote. But now that anarchy corroded the body politic of the disintegrating Russian Empire, the possessing classes of Finland quailed before the rising power of a party which was morally saturated with Marxist doctrines and politically orientated towards Russia. The economic conditions justified the worst fears of the bourgeoisie, for not only had the vehement industrial development of the last three years strengthened the "hooligan element," but the Imperial Legislation Act of 1910 and the conditions of the war had brought a large number of Russians into the country as settlers and even as refugees from famine and nascent revolutionary disorders. Beside the Swedo-Finns (about one-tenth of the population) and the Finnish-speaking Finns there was now this large fluctuating industrial element reinforced by some 40,000 Russian civilians. Apart from these, there were the Russian soldiers who, ever more irregularly paid, bade fair to become a danger to the State.

The Swedish party represented the most conservative elements in Finland, the nucleus of the largest property owners. There was, it

is true, a Swedish branch of the Social Democratic party and also a number of purely Swedish capitalists, yet on the whole the Swedish element was bourgeois and its desire for independence economic since it foresaw the inevitable bankruptcy of Russia.

The Social Democrats, on the other hand, saw in Russia the possible social revolution and intended to go faster than any Miliukov or even Kerensky. Under such conditions the Diet which assembled on April 5 could do as little as the cumbrous governing body of six Social Democrats and six bourgeois representatives.

As far as the Swedish party was concerned, conciliatory relations were to be maintained with Russia until the Peace Conference, but the party congress which was held in May made it clear that independence was the final aim. Even before that the *Hufoudstadibladet* argued that nothing short of complete independence suited the country's needs, and the Finnish Government in the Diet solemnly proclaimed that such was its policy. But this Diet, containing 80% of Social Democrats, 12% of Old and Young Finns, 6% Swedes and 2% Agrarian labourers, the bourgeois did not consider to be truly representative of the nation, on the ground that, at the time of its election in 1916, most people still boycotted the Diet by way of protest against Russian manipulation of the elections; it was only the Socialists who never gave up the class war.

The struggle between the Provisional Russian Government and the Finnish Diet crystallized around the declaration which was embodied in what became known as the "Law of July 18 1917." In this, the Diet resolved that it alone decided, confirmed and put into practice all laws of Finland, including those relating to home affairs, taxation and customs. It made the final decision regarding all other Finnish affairs which the Emperor-Grand Duke decided according to the arrangements hitherto in force, though the provision of this law expressly stated that it did not apply to matters of foreign policy, to military legislation and military administration. The Diet was to meet for regular sittings without special summons and to decide when these were to be closed. Until Finland's new form of government was determined, the Diet was to exercise the right of deciding upon new elections and its dissolution. It asserted its control over the executive power in Finland which was, for the present, to be exercised by the economic department of the Finnish Senate whose members were to be nominated and dismissed by the Diet. This law reflected the standpoint of the Social Democratic majority of the Diet which demanded complete internal and economic freedom for the country, but was always ready to recognize Russia's supremacy in military matters and in foreign policy. The radical group of the Swedish Popular party, aiming further, proposed the following amendment:—"The Diet, which regards it as its right and duty to demand full independence in the name of the Finnish people and reserves in this respect its full freedom of action, resolves, etc." This amendment, however, was rejected by 125 votes to 63, but the motion of the main committee not to submit the new law to the Provisional Russian Government for its sanction was passed by 104 votes to 86. An address was, however, forwarded to the Russian Provisional Government, in which it was expounded that, Finland having always been in relation with the Tsars of Russia but not with any Russian Government, the overthrow of Tsardom had automatically set the country free.

The Russian Provisional Government met this explanation by passing a resolution at the end of July, declaring that under no circumstances would it consent to the separation of Finland from Russia, wherefore it dissolved the Diet and ordered new elections for the beginning of October. The Finnish Diet, however, in its turn, disputed the Russian Provisional Government's right to exercise the prerogative of dissolution, and a deadlock ensued.

*Pourparlers* in Aug. between the Gov.-Gen. Stakovich and the Finnish leaders proved of no avail, although the Russian Federalist Congress in session at Petrograd on the 17th and 18th of that month sought "to work out a basis upon which the Federalists could unite and then prepare for the elections to a Constituent Assembly." Thus the plan for a republic of all the Russias guaranteed autonomy in everything but matters relating to a whole and united Russia.

But it was precisely that which the Finns did not want, anxious as they all were, regardless of party, to avoid taking any part in Russian affairs. Even the Socialists, willing as they were to concede the control of foreign policy and the conduct of military affairs to the larger Power, yet met any kind of representation upon any sort of Russian governing body with a categorical refusal.

In its domestic policy the Social Democratic majority of this Diet was similarly averse to any comprehensive measures of collective reorganization pending events in Russia. Thus the capitalist development of the country was allowed to follow its course. The reform bills passed in recent years and held up by the Tsar were passed *en bloc*, among these the total prohibition of alcohol and the eight-hour day. The municipal councils were democratized and a war bonus was added to the wage of all workers, part being paid by the State and part by the employer. The fixing of maximum prices for food and the control of the supply of fuel, bread, milk, sugar and butter were merely the extension of the work initiated by the pre-revolutionary Senate.

Such action, however, did not strike at the root of the evil, for it was easy to see that a famine threatened the country. Nothing was done to avert it save that large quantities of grain were purchased from America which, owing to difficulties of transit, could not be delivered until starvation and civil war menaced Finland. From about March 1917 to Feb. 1918 there was a veritable strike mania; every trade, every municipal body, every committee even, flung down its job and the Diet and the Senate alike were unable to cope with the situation. The long printers' strike brought it about that from the beginning of July to the middle of Aug. no Moderate papers appeared, though the Social Democrat journals continued to be published. The trouble lay in the dilatoriness of the Russian Provisional Government in confirming the measures passed by the Diet and the Senate which had been hung up by the Tsar since 1910. The All-Russian Congress of Workers and Soldiers, which was already under Bolshevist influence, had met early in July and urged the Provisional Government to grant full autonomy to Finland and all executive power to the Diet, which action gained it the sympathy of the Finnish Socialists. A "general strike" was called for against the wishes of Tokoi and Manner, and the Diet was to reassemble despite the threats of the governor-general that its doors would be guarded and sealed. After two or three days of disturbances, this ill-considered move collapsed, but the Russian Provisional Government proposing that the economy department of the Finnish Senate should have the supreme power, Tokoi dissolved the governing body composed of six Social Democrats and six Bourgeois representatives because it was too evenly balanced for effective administrative work. Thereupon the Socialist senators resigned while the Moderates were induced to form a Senate. This was regrettable, as the Russian Provisional Government now gave way, and on Aug. 24 ratified a number of the reform measures passed by the Diet and Senate between 1911 and 1914. A day later the Moscow conference, under Menshevik influence, expressed its desire to retain all power over Finland which the restored constitution allowed.

Meanwhile the failure of the general strike and the appointment of Nekrasov as governor-general in place of Stakovich influenced the elections for the Diet which, completed by Oct. 2 1917, proved a setback to the Social Democrats and caused the Old and Young Finns, the Swedes and the Agrarians to form a Moderate *bloc* of 108 members. The absorbing controversy, whether the Senate (through its economy department) was to hold the supreme power or the Diet, was settled on Nov. 15 by Alkio, the leader of the Agrarians, in favour of the latter, and on Nov. 28 a Moderate Senate of eleven members was elected. Still, however, nothing was done to increase the food production. Though countered by the Moderate coalition, the Social Democrats were still the strongest individual party in the House, and would have had the bulk of the people behind them if they had been able to seize and nationalize the land. The economic conditions, beyond a doubt, rendered this task very difficult, for in Finland, as in Russia, the cultivation of the soil was carried on individually and the transfer to the State would have been a delicate operation.

The Bolshevist advent to power in Russia between Nov. 4 and 15 1917 deepened the pro-Russian sympathies of the Finnish Social Democrats who had been alienated by Kerensky's equivocal policy, while the bourgeois parties, arguing that there was now no settled government in Russia, desired complete independence. On Dec. 6 1917 the Diet and the now bourgeois Senate drew up a very old-fashioned declaration of independence which, however, historically marks the birth of Finnish freedom. As the Socialists still sought an understanding with Russia, the bourgeois *bloc*, which governed the situation since it had furnished the new administration at the beginning of the month, acting with great haste sent the declaration to Sweden and Germany at once. Both these Powers replied that Finland must first obtain full recognition of her independence from Russia. The Diet then decided to approach the Constituent Assembly in Russia through a friendly manifesto which explained that the assertion of independence was not a hostile act and that a joint committee would settle outstanding questions so that Russia could proceed with her war without fear of trouble from Finland. But as the Constituent Assembly was not allowed to meet, the Finnish Senate finally appealed to the Bolshevist Government and was informed on Jan. 4 1918 that the steps taken conformed with the policy and programme of the Bolshevists. Immediately afterwards the Swedish Government recognized the independence of Finland and was followed by the other Scandinavian countries. Recognition by France preceded recognition by Germany.

*The Finnish Civil War Feb.–May 1918.*—At this time the social and economic differences between the political parties were too deep to admit of an easy settlement. The possessing classes,—that is to say primarily the Swedo-Finn and Finno-Finn bourgeoisie, but especially the first-named—rather than see the wealth amassed during three years of the World War taken from them by the rising Social Democrats, were jeopardizing the newly won independence, now by intrigues which aimed at the cession of the Aland Is. to Sweden, now by manœuvres which tended to set Finland under the heel of Germany. The Moderate *bloc* to which the Swedo-Finns adhered was anyhow determined to break away from Russia, and its leaders openly discussed the chances of union with Sweden on the one hand and the adoption of some German prince as grand duke on the other.

Apart from that, there were some Finnish contractors who had allowed the Russian Government credit for the provision of war material, food and clothing, and did not desire to incur the loss

which a complete rupture of relations was certain to entail. They therefore stood for the maintenance of the connexion with Russia.

Principally, however, the Social Democrats believed that Socialist governance had come to stay in Russia, and they were not minded to protect Finnish capital from seizure if the birth of a coöperative commonwealth in Finland could thereby be accelerated. When the Bolshevist *coup d'état* in Russia became known, they unwisely fraternized with the Russian soldiers stationed in Finland, and with their help rejected municipal bodies and replaced them by Social Democrat committees. Such action was hardly designed to relieve the ever-growing food difficulties and laid their party open to the reproach of harbouring anarchical tendencies. The Socialists were almost all Maximalists and anti-militarists, and, as such, averse even to the formation of a democratic citizen army maintained for purposes of order and defence. They pinned their faith on the Muscovite connexion to save their country from invasion—oblivious of the fact that the Russian soldier, freed of the restraints of a discipline which had become his second nature, starving and unpaid, was, to say the least, an uncertain factor. While free passes were given, whole trainloads of revolutionary *soldateska* arrived from Petrograd nominally to assist the Socialists in their active differences with the bourgeoisie, but in reality to create disturbances. Having massacred their officers and any bourgeois elements which remained among them, they entered the so-called Finnish "Red Guards," and ransacked the country. The reactionaries, getting together the doubtful elements of the disbanded *gendarmerie* and their own adherents, organized the "White Guards." German arms and explosives were imported by one side; Russian bayonets by the other. At Christmas 1917 matters came to a head at Åbo, where the Social Democrats imprisoned the governor and the chief of the police. For about a week the "Red Guards," which were composed of casually armed Social Democrats, remained on duty notwithstanding the fact that their pay had been suspended by the local Moderate bourgeois authorities. Then they gave up their job, and Russian troops and "hooligan elements" seized the opportunity to sack a part of Åbo. After some days' disorders, hurriedly summoned "Whites" from another district and some of the original "Reds" restored order together. But the bourgeois *bloc* neglected to introduce a democratic citizen army and opposed the reactionary efforts of the Swedish party to form a conscript army round the nucleus "White Guards."

The Bolsheviks were clearly bent on precipitating civil war in Finland, and poured arms, munitions and troops into the country for the ostensible purpose of helping the Social Democrats. For this reason the Senate on Jan. 29 addressed a protest against the action of the Russian Government to the various Powers which had recognized Finnish independence. But it was too late, as now even the sanest Social Democrats were swept into a flood of Bolshevism. Helsingfors on that very day was seized by the Red Guards and by Feb. 8 1918 the *coup d'état* had occurred and "Whites" and "Reds" were in brutal conflict everywhere.

*The German Intervention, March–May 1918.*—The Diet belatedly adopted, on Jan. 17 1918, certain measures suggested by Senator Kaarlo Castrén for the strengthening of the White Guard formations. As these were insufficient to save the White army, which was under the command of the former Russian general of cavalry, Baron Carl Gustav Emil Mannerheim, the necessity arose of seeking foreign intervention. As regards this it is known from the Swedish statesman Branting that the Finnish Government, when it "made its official proposal for a Swedish intervention . . . . . had simultaneously asked in Berlin for a German armed intervention." Thus Sweden, had she assented, would have been dragged into the war, as "nobody can imagine that Germany would have refused an offer so favourable to her hegemony in the Baltic."

This judgment is true, for while Sweden refused official help, the Germans did not hesitate. After all, they had kindled the Bolshevist fires in the East and sent war material into Finland for the express purpose of fomenting troubles which they could exploit to their own advantage. The situation was favourable to them, for as Mr. E. Löfgren, Minister of Justice in the Swedish Coalition Government of 1918, publicly explained, "the Finns immediately after the declaration of their independence had entered into negotiations for a treaty with Germany, which in a commercial political sense made Finland the ally and vassal of Germany. . . ." The allusion is to the Finno-German treaty of March 7 1918.

But since the public knew little of the underground workings of German policy, the landing of a German composite division in the Åland island of Ekerö on March 3 and in Finland by April 3 caused the Prussian general officer commanding, Count Rüdiger von der Goltz, to be hailed as the liberator of the country. He had initially some 12,000 men under his orders, viz., three dismounted cavalry regiments, three Jäger battalions, Bavarian mountain artillery, two heavy batteries, a squadron of cavalry, and sundry technical and supply formations which were subsequently reinforced by the detachment "Brandenstein," consisting of three infantry battalions, one cyclist battalion, a squadron of cavalry and two batteries. He had further the support of the German navy in the landing operations, and the remnant of the 2,000 Finnish exiles who had joined the German army in 1915–6 and made up the famous "27th" Jägers, who were as well drilled in Pan-Germanism as in military science, Gen. von der Goltz, by landing in the rear of the Red forces and holding part of these in a successful action near Karis on April 6, enabled Gen. Mannerheim to win the battle of Tammerfors, while he himself, by a rapid advance on Helsingfors, between April 11 and 13, freed this capital which he officially entered on April 14. Finally his victory over the Reds in the three days' battle (April 30–May 2) of Lahti-Tavastehus contributed to Mannerheim's decisive defeat of the Red eastern army near Viborg on April 28–29. The remnants of the Red army being forced eastwards into Russia, the campaign ended in a month with the complete victory of the Whites.

The terrible cruelty of the Reds, however, led to the White Terror as the price the country had to pay for being dragged into "Mittel-Europa." Some 15,000 men, women and children were slaughtered in cold blood, and by June 27 1918 73,915 Red insurrectionaries, including 4,600 women, were prisoners of war.

The Diet, which met in June 1918, was Moderate, since the Socialists or 46% of the electorate were excluded from the register. It authorized Senator Pehr Evind Svinhufvud, who under the Russian régime had been an exile from his country, to exercise the supreme power in so far as it had not already been conferred on the Senate which was bringing forward proposals for a monarchical form of government by offering the crown to Prince Frederick Charles of Hesse, brother-in-law of the German emperor.

But the Germans pursued the ulterior object of securing Finnish military coöperation against the Murman railway, which, having been built by English enterprise during the war, was now guarded by a British expeditionary force. The claim of the liberators upon the gratitude of the Finns was assuming the most peremptory forms known to diplomacy, when, three days later, on July 18, events took place on the western front which marked the turn of the war to Germany's disadvantage. One collision between a Finnish force and a detachment commanded by a British officer, Lt. Quinn-Harkin, occurred in northern Karelia, but valuable time was gained until the rapid transformation of the European war, culminating in the Armistice of Nov. 11 1918, caught Finnish reaction between wind and water. Svinhufvud, the pliant tool of Germany, relinquished the supreme power, and was succeeded on Dec. 12 by Gen. Mannerheim as regent, who formed a Coalition Government composed of six Republicans and six Monarchists. The persons discredited by their extreme pro-Germanism, among them Gen. Thesleff, the Minister of War, were replaced in order to obtain the recognition of Finland by the Great Powers and secure the food supply of which the country stood in need. The definite orientation towards the Entente marked the transition from the monarchist period of German influence towards the democratic régime associated with England and America.

The German troops, in part mutinous, were conveyed back to Germany in the middle of Dec., but with difficulty, as the German navy refused to transport units which had remained faithful to the Emperor. Gen. Mannerheim, who as regent wielded the power of a quasi-dictator, was a monarchist, but not a pro-German.

*Events in 1919 and 1920.*—The year 1919 witnessed the growth of the Republic of Finland out of the ashes of a country laid waste by civil war. Mannerheim organized the "Skyddskorps" or Protective Guards, a body of over 100,000 men, whose loyalty to the existing order of society could be relied upon.

The general election of March 1 1919 showed the following division of parties: Social Democrats 80, Agrarians 42, Coalitionists 28, Progressives 26, Swedish 22, Christian Labour two. The Social Democrats had thus diminished by 12 since the 1917 elections. This was largely attributable to the disfranchisement of over 40,000 voters for participation in the Red revolt. The tendency towards a republican form of government was outlined by the Agrarian party, composed of small landowners hostile to the claims of the Swedish-speaking Monarchist section.

Mannerheim's popularity being immense with the parties of the Right and the army, the temptation of exploiting the military impotence of Soviet Russia was very great. In 1919 continued the Entente intervention on the Murmansk and Archangel fronts, and when the 237th Brigade (Gen. Price), which formed part of the expeditionary force under the English Maj.-Gen. Maynard, at the end of May reached Medvyejva Gora at the head of Lake Onega, the Finnish Government offered coöperation in return for the possession of Petrozavodsk. The offer being declined, a Finnish volunteer force nevertheless assaulted the town independently, but without success. Again, at the close of the year, when the White-Russian Gen. Judenitch was marching on Petrograd, Mannerheim went so far as to sound the Allies as to their views on the proposed Finnish intervention. But he received no encouragement from Paris or London, nor from the Moderates at home.

Already on July 17 of that year the Finnish Diet had resolved to establish a republic, with a president to be elected every six

is true, a Swedish branch of the Social Democratic party and also a number of purely Swedish capitalists, yet on the whole the Swedish element was bourgeois and its desire for independence economic since it foresaw the inevitable bankruptcy of Russia.

The Social Democrats, on the other hand, saw in Russia the possible social revolution and intended to go faster than any Miliukov or even Kerensky. Under such conditions the Diet which assembled on April 5 could do as little as the cumbrous governing body of six Social Democrats and six bourgeois representatives.

As far as the Swedish party was concerned, conciliatory relations were to be maintained with Russia until the Peace Conference, but the party congress which was held in May made it clear that independence was the final aim. Even before that the *Hufoudstadibladet* argued that nothing short of complete independence suited the country's needs, and the Finnish Government in the Diet solemnly proclaimed that such was its policy. But this Diet, containing 80% of Social Democrats, 12% of Old and Young Finns, 6% Swedes and 2% Agrarian labourers, the bourgeois did not consider to be truly representative of the nation, on the ground that, at the time of its election in 1916, most people still boycotted the Diet by way of protest against Russian manipulation of the elections; it was only the Socialists who never gave up the class war.

The struggle between the Provisional Russian Government and the Finnish Diet crystallized around the declaration which was embodied in what became known as the "Law of July 18 1917." In this, the Diet resolved that it alone decided, confirmed and put into practice all laws of Finland, including those relating to home affairs, taxation and customs. It made the final decision regarding all other Finnish affairs which the Emperor-Grand Duke decided according to the arrangements hitherto in force, though the provision of this law expressly stated that it did not apply to matters of foreign policy, to military legislation and military administration. The Diet was to meet for regular sittings without special summons and to decide when these were to be closed. Until Finland's new form of government was determined, the Diet was to exercise the right of deciding upon new elections and its dissolution. It asserted its control over the executive power in Finland which was, for the present, to be exercised by the economic department of the Finnish Senate whose members were to be nominated and dismissed by the Diet. This law reflected the standpoint of the Social Democratic majority of the Diet which demanded complete internal and economic freedom for the country, but was always ready to recognize Russia's supremacy in military matters and in foreign policy. The radical group of the Swedish Popular party, aiming further, proposed the following amendment:—"The Diet, which regards it as its right and duty to demand full independence in the name of the Finnish people and reserves in this respect its full freedom of action, resolves, etc." This amendment, however, was rejected by 125 votes to 63, but the motion of the main committee not to submit the new law to the Provisional Russian Government for its sanction was passed by 104 votes to 86. An address was, however, forwarded to the Russian Provisional Government, in which it was expounded that, Finland having always been in relation with the Tsars of Russia but not with any Russian Government, the overthrow of Tsardom had automatically set the country free.

The Russian Provisional Government met this explanation by passing a resolution at the end of July, declaring that under no circumstances would it consent to the separation of Finland from Russia, wherefore it dissolved the Diet and ordered new elections for the beginning of October. The Finnish Diet, however, in its turn, disputed the Russian Provisional Government's right to exercise the prerogative of dissolution, and a deadlock ensued.

*Pourparlers* in Aug. between the Gov.-Gen. Stakovich and the Finnish leaders proved of no avail, although the Russian Federalist Congress in session at Petrograd on the 17th and 18th of that month sought "to work out a basis upon which the Federalists could unite and then prepare for the elections to a Constituent Assembly." Thus the plan for a republic of all the Russias guaranteed autonomy in everything but matters relating to a whole and united Russia.

But it was precisely that which the Finns did not want, anxious as they all were, regardless of party, to avoid taking any part in Russian affairs. Even the Socialists, willing as they were to concede the control of foreign policy and the conduct of military affairs to the larger Power, yet met any kind of representation upon any sort of Russian governing body with a categorical refusal.

In its domestic policy the Social Democratic majority of this Diet was similarly averse to any comprehensive measures of collective reorganization pending events in Russia. Thus the capitalist development of the country was allowed to follow its course. The reform bills passed in recent years and held up by the Tsar were passed *en bloc*, among these the total prohibition of alcohol and the eight-hour day. The municipal councils were democratized and a war bonus was added to the wage of all workers, part being paid by the State and part by the employer. The fixing of maximum prices for food and the control of the supply of fuel, bread, milk, sugar and butter were merely the extension of the work initiated by the pre-revolutionary Senate.

Such action, however, did not strike at the root of the evil, for it was easy to see that a famine threatened the country. Nothing was done to avert it save that large quantities of grain were purchased from America which, owing to difficulties of transit, could not be delivered until starvation and civil war menaced Finland. From about March 1917 to Feb. 1918 there was a veritable strike mania; every trade, every municipal body, every committee even, flung down its job and the Diet and the Senate alike were unable to cope with the situation. The long printers' strike brought it about that from the beginning of July to the middle of Aug. no Moderate papers appeared, though the Social Democrat journals continued to be published. The trouble lay in the dilatoriness of the Russian Provisional Government in confirming the measures passed by the Diet and the Senate which had been hung up by the Tsar since 1910. The All-Russian Congress of Workers and Soldiers, which was already under Bolshevist influence, had met early in July and urged the Provisional Government to grant full autonomy to Finland and all executive power to the Diet, which action gained it the sympathy of the Finnish Socialists. A "general strike" was called for against the wishes of Tokoi and Manner, and the Diet was to reassemble despite the threats of the governor-general that its doors would be guarded and sealed. After two or three days of disturbances, this ill-considered move collapsed, but the Russian Provisional Government proposing that the economy department of the Finnish Senate should have the supreme power, Tokoi dissolved the governing body composed of six Social Democrats and six Bourgeois representatives because it was too evenly balanced for effective administrative work. Thereupon the Socialist senators resigned while the Moderates were induced to form a Senate. This was regrettable, as the Russian Provisional Government now gave way, and on Aug. 24 ratified a number of the reform measures passed by the Diet and Senate between 1911 and 1914. A day later the Moscow conference, under Menshevik influence, expressed its desire to retain all power over Finland which the restored constitution allowed.

Meanwhile the failure of the general strike and the appointment of Nekrasov as governor-general in place of Stakovich influenced the elections for the Diet which, completed by Oct. 2 1917, proved a setback to the Social Democrats and caused the Old and Young Finns, the Swedes and the Agrarians to form a Moderate *bloc* of 108 members. The absorbing controversy, whether the Senate (through its economy department) was to hold the supreme power or the Diet, was settled on Nov. 15 by Alkio, the leader of the Agrarians, in favour of the latter, and on Nov. 28 a Moderate Senate of eleven members was elected. Still, however, nothing was done to increase the food production. Though countered by the Moderate coalition, the Social Democrats were still the strongest individual party in the House, and would have had the bulk of the people behind them if they had been able to seize and nationalize the land. The economic conditions, beyond a doubt, rendered this task very difficult, for in Finland, as in Russia, the cultivation of the soil was carried on individually and the transfer to the State would have been a delicate operation.

The Bolshevist advent to power in Russia between Nov. 4 and 15 1917 deepened the pro-Russian sympathies of the Finnish Social Democrats who had been alienated by Kerensky's equivocal policy, while the bourgeois parties, arguing that there was now no settled government in Russia, desired complete independence. On Dec. 6 1917 the Diet and the now bourgeois Senate drew up a very old-fashioned declaration of independence which, however, historically marks the birth of Finnish freedom. As the Socialists still sought an understanding with Russia, the bourgeois *bloc*, which governed the situation since it had furnished the new administration at the beginning of the month, acting with great haste sent the declaration to Sweden and Germany at once. Both these Powers replied that Finland must first obtain full recognition of her independence from Russia. The Diet then decided to approach the Constituent Assembly in Russia through a friendly manifesto which explained that the assertion of independence was not a hostile act and that a joint committee would settle outstanding questions so that Russia could proceed with her war without fear of trouble from Finland. But as the Constituent Assembly was not allowed to meet, the Finnish Senate finally appealed to the Bolshevist Government and was informed on Jan. 4 1918 that the steps taken conformed with the policy and programme of the Bolshevists. Immediately afterwards the Swedish Government recognized the independence of Finland and was followed by the other Scandinavian countries. Recognition by France preceded recognition by Germany.

*The Finnish Civil War Feb.–May 1918.*—At this time the social and economic differences between the political parties were too deep to admit of an easy settlement. The possessing classes,—that is to say primarily the Swedo-Finn and Finno-Finn bourgeoisie, but especially the first-named—rather than see the wealth amassed during three years of the World War taken from them by the rising Social Democrats, were jeopardizing the newly won independence, now by intrigues which aimed at the cession of the Aland Is. to Sweden, now by manœuvres which tended to set Finland under the heel of Germany. The Moderate *bloc* to which the Swedo-Finns adhered was anyhow determined to break away from Russia, and its leaders openly discussed the chances of union with Sweden on the one hand and the adoption of some German prince as grand duke on the other.

Apart from that, there were some Finnish contractors who had allowed the Russian Government credit for the provision of war material, food and clothing, and did not desire to incur the loss

An Education bill was introduced by him Aug. 10 1917, the most noteworthy proposals of which were the removal of the limit of the 2d. rate which might be raised by local authorities for education, the establishment of nursery schools for children under five, the amending of the law of school attendance, the placing of further restrictions upon the employment of children of school age, the improvement of measures for physical training, and the establishment of continuation schools for young people up to the age of eighteen (*see* EDUCATION).

Mr. Fisher has published *The Mediaeval Empire* (1898); *Studies in Napoleonic Statesmanship* (1903); *A Political History of England* (1906); *Bonapartism* (1908); *Life of F. W. Maitland* (1910); *The Republican Tradition in Europe* (1911); *Political Unions* (1911) and *Napoleon Bonaparte* (1913); besides essays and review articles.

**FISHER, IRVING** (1867– ), American economist, was born at Saugerties, N.Y., Feb. 27 1867. He studied at Yale (A.B. 1888), Berlin, and Paris. He at first taught mathematics at Yale; but in 1895 was made assistant professor of political economy, and in 1898 professor. He was editor of the *Yale Review*, 1896–1910. He served as chairman of many commissions dealing with public health, prohibition, and labour. An authority on money inflation, he proposed that the purchasing power of the dollar be stabilized (*see* DOLLAR STABILIZATION). His plan was to replace coined gold dollars by "gold bullion dollar certificates" which should command such weight of gold bullion as might legally be declared to constitute a dollar at that particular time. The weight of this ideal gold dollar would be adjusted at intervals in accordance with its power to purchase commodities as shown by the "index number" of prices.

His writings include: *Mathematical Investigations in the Theory of Value and Prices* (1892); *Elements of Geometry* (with A. W. Phillips, 1896); *A Brief Introduction to the Infinitesimal Calculus* (1897); *The Nature of Capital and Income* (1906); *The Rate of Interest* (1907); *National Vitality* (1909); *The Purchasing Power of Money* (1911); *Elementary Principles of Economics* (1913); *Why is the Dollar Shrinking?* (1914) and *Stabilizing the Dollar* (1919).

**FISHER, JOHN ARBUTHNOT,** 1ST BARON (1841–1920), British admiral (*see* 10.428), on relinquishing the office of First Sea Lord in Jan. 1910 remained in retirement until 1912, when he was appointed chairman of the royal commission on oil fuel. He was a firm believer in oil as fuel for the navy, with its corollary the internal combustion engine. He foresaw its effects on the design of war vessels, and the far-reaching tactical results to be derived from the employment of capital ships that would show no funnels or smoke, have immense sea-keeping powers, and be fuelled at sea from tankers.

After the outbreak of the World War, the retirement of Prince Louis of Battenberg, in Nov. 1914, from the post of First Sea Lord, led to Lord Fisher's being again installed in that office at the Admiralty. His presence was immediately felt in the dramatic and brilliant piece of strategy which resulted, under Admi. Sturdee, in the destruction of Admi. von Spee's squadron off the Falklands. Fisher then, with the coöperation and hearty support of Mr. Churchill, initiated a great building programme of cruisers, monitors, destroyers and small craft to the number of some 600 keels, pressing the American shipyards into the service, necessarily at an enormous cost. Everything had to be subordinated to haste, and in fact most of the craft were actually delivered within six months. Although primarily designed for a great strategic move into the Baltic, which Lord Fisher had himself drawn up in detail, this vast armada was gradually diverted from its original purpose to various other uses—among them the naval attempt to force the passage of the Dardanelles; and it was the War Council's decision to proceed with this that ultimately (May 1915) led to Lord Fisher's resignation of his post as First Sea Lord. In the following July he was appointed chairman of the Inventions Board, and in 1917 gave important evidence before the Dardanelles Commission. In 1919 he published two books—*Memories* and *Records*. These collections of unconventional and more or less fragmentary utterances taken down in shorthand inevitably suffer from a lack of sequence and coherence, and they are of little value as a guide to their author's actual achievements. After some months of illness Lord Fisher died on July 10 1920, his last public act being a press campaign in favour of economy. He was then in his eightieth year.

It was still difficult in 1921 to form a just estimate of the value to his country of Lord Fisher's long and arduous service. In some ways the results of his strenuous life were disappointing to himself and to those whom his strong and rugged personality impressed with a sense of almost superhuman genius and power; as well as to those, such as the journalists whom he knew well how to flatter, who took him exactly at his own valuation. It needed an experience like that of the late King Edward to see the weak and unprotected places in the strong man's armour, and to understand where what was fine in him needed support and protection. Like so many men in his service, Lord Fisher suffered from the disadvantages of an incomplete education—a defect not likely to be felt in actual fighting service, but apt to become more and more of a handicap as a man advances in his profession and deals with wider and more complex problems than those involved in merely technical developments. Lord Fisher was temperamentally as well as by training unable to make use of a staff, in the modern sense of that term; he thought alone, formulated his large but vague conceptions of war and strategy alone, and attempted practically alone to work them out—with inevitable results. It is remarkable that so powerful and in some ways attractive a personality neither produced any school nor influenced any notable group in the navy; and even of the men whom he selected and furthered, practically none except Lord Jellicoe came to great distinction or achieved any signal success. Many of the schemes with which his name is most closely associated—Osborne, the training of the engineering branch, the system of the "common entry" for example—proved failures and had to be abandoned or completely remodelled. Although he was sponsor while First Sea Lord for the Dreadnought principle of design, and for such infinitely important technical developments as water-tube boilers, turbines, etc., his theory that "speed is armour," as applied to North Sea warfare, proved to be dangerous, and the battle cruisers designed in accordance with it were to some extent at a disadvantage as a result of reliance on aphorism rather than on the logical and thought-out harmonization of means, conditions and end. Some of the more extreme examples of this class, still under construction on his retirement from the Admiralty, had to be abandoned or altered or adapted to other uses. On the other hand, in his large conceptions of warfare, in his prevision of the war with Germany and its date, in his concentration of the navy in the North Sea as a training ground, in his strategical strokes, such as the destruction of the von Spee squadron, and his conception of a Baltic campaign early in the war (never carried out), and in his untiring advocacy of an offensive policy (also overruled), Lord Fisher showed a true genius and grasp of the essentials of naval warfare which alone would make him a memorable figure in British history. His character was a combination of strength, ingenuity and simplicity; by some mysterious throwback he had, both physically and mentally, a strong oriental strain in his composition; and the Bible was his favourite and most familiar book. He read, however, not so much to educate and enlarge his mind, as to seek and find confirmation of his own views and conceptions of things. In that respect he was like a great artist, who assimilates everything in life that will contribute to the endorsement and magnification of his own genius, and rejects the rest. He was sometimes ruthless and violent in his methods, although rather less so than he would have the world believe; there were indeed veins of beauty and modesty in his character, and he came nearest to true greatness when he was most simple. His were a life and character essentially of the kind to provoke violent controversy and sharp divisions between his admirers and accusers; but when these have died away his figure will stand out, even among the strong men of his day, as that of an enemy to shams and pretences, to sloth and incompetency, and as a passionate lover and defender of his country. (F. Y.)

**FITZMAURICE-KELLY, JAMES** (1858– ), English man of letters, was born at Glasgow June 20 1858. Educated at St. Charles's College, London, he became Taylorian lecturer in

Spanish at Oxford in 1902 and Gilmour professor of Spanish language and literature from 1909 to 1916, when he was transferred to London as Cervantes professor of Spanish language and literature to the university of London. This post he resigned in 1920. He became a fellow of the British Academy and corresponding member of the Royal Spanish Academy and other Spanish societies, and a Knight Commander of the Order of Alphonso XII. Amongst his publications are a *Life* of Cervantes (1892); an Introduction to the editio princeps of *Don Quixote* (1898–9); a *History of Spanish Literature* (1898); *Cervantes in England* (1905); *Cervantes and Shakespeare* (1916) and many other books and papers.

**FLAMETHROWERS** (Germ. *Flammenwerfer*).—The World War revived the old weapon of "liquid fire." No doubt, the use of incendiary projectiles and devices had never altogether vanished from modern warfare, but these have usually been employed for destruction of material rather than for effect on personnel, and we have to go back to the sieges of mediaeval times to find examples of the use of heat, as such, to repulse an enemy. The townspeople of a mediaeval city, having only massacre to expect if their walls were stormed, observed no limitations in their choice of weapons, and not only used incendiaries proper to destroy the besiegers' hoarding-work and catapults but also boiling oil against the bodies of the men. From time to time in modern history proposals have been made for flame-throwing devices, and one such was actually experimented with in Prussia about 1700. But until modern methods of storing a gas propellant under pressure came into being, anything in the nature of an effective flamethrower was impossible.

In reality therefore the flamethrower dates from experiments made in Germany a few years before the World War, when, no doubt in consequence of the trench warfare of Port Arthur, Richard Fiedler produced in 1906 a service model which was under experiment when the war broke out. Like other weapons of siegecraft this was brought into the field as soon as the nature of the fighting changed from open-field warfare to trench warfare. Already in the winter of 1914–5 they appeared sporadically on the western front, and they obtained their first striking success in the Bois d'Avocourt (Verdun) on Feb. 26 1915. It should be noted that the use of such weapons was not prohibited by the Hague Convention, save in so far as it might be called a weapon "calculated to cause unnecessary suffering"—a phrase which is susceptible of many interpretations. In this it differed from the gas warfare initiated at Ypres in April 1915, although by the accident of circumstances gas and flamethrowers have come to be associated in the popular mind.

When the German *Flammenwerfer* appeared it was considered essential both in France and in England to design weapons of this class at once; in England the question of their employment was reserved, but it was felt that the soldiers who were exposed to flame attack should, for reasons of *moral*, be made aware that similar devices were available on their own side. In France the military authorities proceeded without hesitation to the creation not only of the apparatus but of the units to work them. This difference in the way in which flamethrowers were regarded in the two chief Allied countries persisted to the end of the war. The French used them as constantly as the Germans, whereas in the British Army their employment on service was limited to a very few occasions in the battle of the Somme, and to the Zeebrugge attack of St. George's Day 1918. By the American Expeditionary Force they were not used at all, though the question of their employment was taken into consideration. In 1919 they figured largely in the local street-fighting by which the German Republic made good its authority.

The flamethrower essentially consists, in all designs, of (*a*) a container filled with some mixture of heavy and light oils; (*b*) a strong-walled vessel filled with air, nitrogen, $CO_2$, etc., under high pressure; and (*c*) a discharge tube with nozzle and in most cases an ignition device. Between (*a*) and (*b*) is a reducing valve, and between (*b*) and the nozzle a firing valve or trigger. When air or gas under high pressure is admitted into (*a*) from (*b*) it expels through (*c*) a powerful jet of oil, which when ignited (either at the nozzle or subsequently) becomes "liquid fire."

Flamethrowers are essentially short-range weapons, whose characteristic effect is to make an area untenable by living beings, by actual burning and also by heating the surrounding air to an intolerable temperature. This effect imposes, as a condition of their use, maximum range, not only because range as such is a desirable military quality but because the operators themselves must not be put out of action by their own weapon. Range, however, is difficult to obtain with a liquid jet. Even *in vacuo* such a jet with an initial velocity of 50 metres per second would not theoretically range to 300 yd., and, owing to the resistance of the air, the maximum range ever known to have been attained in practice was 134 yd. actual throw (with an experimental British type of heavy flamethrower). Beyond the actual range of the jet there is of course an area (which varies according to the conditions of the shoot) made momentarily untenable owing to the heating of the air, and this area extends laterally as well as forward. But the fact of limited range remains a constant drawback. It is especially pronounced with the light portable types, few of which outrange the hand-grenade.

Amongst the design factors influencing initial velocity and therefore range, two are of principal importance, the pressure of the gas propellant in the oil container and the loss of energy in the discharge pipe and nozzle. The first would seem, at first sight, to be limited only by the weight and strength of the containers—those of the gas "bottle" in the first instance and those of the oil container secondarily. But in practice the size of the nozzle orifice sets an upper limit to working pressure; if it is too small in proportion to the pressure the liquid, instead of being propelled in a consistent jet, is atomised and loses its forward energy very soon. But the larger the orifice the greater the quantity of liquid discharged per unit time. Hence, to obtain a long throw of any useful duration the flamethrower must be large, heavy and cumbrous. Conversely, when minimal weight is important, either range or duration must be sacrificed. Up to the limit thus fixed, of course, maximal pressure is aimed at in design, and it is found that, with modern materials and workmanship, gas bottles capable of standing the unreduced or storage pressure and oil containers able to endure the reduced or working pressure can be constructed within practicable weights.

The second important factor is loss of head, which varies with the length and smoothness of the internal surface of the discharge system, and is affected still more by the occurrence of abrupt bends and contractions in the piping or nozzle. A discharge system as straight, as short, and as large in bore as possible is therefore aimed at. But here again practical limits exist. In all heavy and medium and in most "knapsack" flamethrowers the position of the container has no relation to the axis of the jet. It is not, like a gun, pointed in the direction of the target, but is built in under cover or stood up on the ground or carried on a man's back, and aim is taken by pointing the nozzle only. Hence the most that can be done is to smooth out the angles of bend as much as possible and to diminish the length of piping to the strict minimum. Large bore is always desirable but not always attainable, since increased volume of oil per unit time means either increased dimensions for the oil container or diminished duration of action without reloading.

The dimensions of the nozzle itself, in this connexion, are important as affecting the form of the jet. Progressively, in its passage through the air, the solid vein of liquid breaks up into globules and loses its forward energy; the higher the initial velocity the longer this break-up is delayed, and velocity is, as we have seen, a function of working pressure and orifice dimensions. Moreover, the larger the vein itself the less surface it presents to disintegration by the air for a given volume; and the same reasoning excludes all cross-sections of the nozzle other than circular.

The oils employed varied, in the World War, according to available supplies, but were always in principle mixtures of heavy oil and light oil (petrol or benzol), the former for the sake of maintaining forward energy in the air (giving "sectional density" in ballistic language), the latter for ease of ignition. In winter the proportion of light oil was increased up to one-third in the French service.

The propellant gases used were also varied. Compressed air, being most readily available, was probably the most frequently employed. The Germans even tried compressed oxygen, a most dangerous expedient when nozzle-ignition is employed, as the mixture in the interior of the container is liable to detonate if a back flame from the jet reaches it.[1] This risk attaches also in a lesser degree to compressed air, and inert gases are always preferable. $CO_2$ has the disadvantage that it forms a deposit in the piping and so increases loss of head, and in the end nitrogen—either the pure product of chemical factories or a "deoxygenated air" produced in the field by a mobile plant—was generally accepted.

So far only the expulsion of the oil jet has been considered. Broadly, there are two forms of ignition. In the one the ground occupied by the enemy is sprayed with the unignited oil, and then fired by throwing on to it incendiary bombs or grenades. This is mechanically the simplest way, and it gives the most thorough effect, since all parts of the ground, even the floors of trenches, are set on fire. But the throwing of grenades on to the correct spot is a difficult

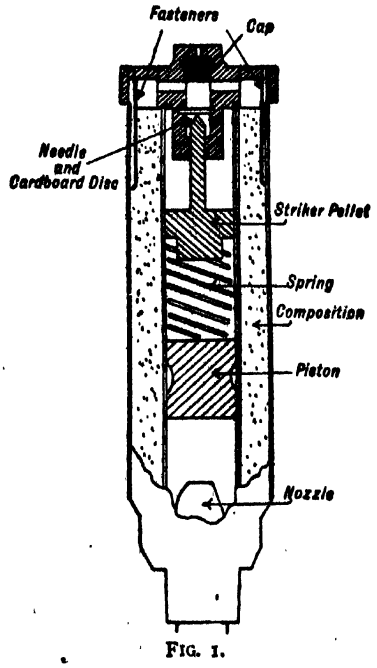
[1] A very serious accident occurred on one occasion in England from this cause, an oxygen bottle having been accidentally substituted for an air bottle.

matter, especially with the long-range heavy flamethrowers, and surprise effect—which, in the opinion of some, is the principal if not the only asset of the weapon—is entirely lost. The other method is to fix an igniter to the nozzle; this fires the jet at the outset, ensures surprise and moral effect, for the liquid-fire jet, with its roar, its heat, and heavy smoke intermingled with darting masses of flame, is a terrifying thing. On the other hand nozzle-ignition presents very difficult problems which have never been satisfactorily solved, and the actual burning effect is more local than is the case with the simpler method. On the whole nozzle ignition is to be preferred whenever a reasonably certain ignition device is available. The French made use of both methods, the Germans and British exclusively, or almost exclusively, of nozzle ignition. It was at one time supposed that the unignited jet ranged farther than the flaming jet, but this is not proved. French experiments indicate that what is lost in "sectional density" by igniting the jet is regained by the fact that the surrounding air, heated to a high temperature, offers a lessened resistance.

Ignition devices may be simple portfires (or even petrol-soaked wads) attached by hand to the nozzle and ignited before aim is taken, or more elaborate electrical and mechanical devices. In all cases they are required to ignite, not the oil itself, which emerges in too rigid a column to respond to the spark, but the film of petrol vapour which forms round the column. The spark must be emitted by the igniter as close as possible to the emerging jet without actually touching it. Moreover it must be protected against the wind. Further, the igniter must remain alight and in the correct position during the duration of the throw; this condition is very difficult to satisfy in the case of portable flamethrowers which operate by a succession of short, sharp jets controlled by a trigger, save by the clumsy expedient of a long-burning portfire. Amongst the many forms of ignition three may be specially mentioned:—

(*a*) A British pattern in which two sparking-plugs were mounted in a cup containing petrol, and fired by a magneto generator.

(*b*) A French type, giving the very long burning required for the successive shots of the portable flamethrowers by means of a tubular magazine fixed to the nozzle. In this magazine was a long stick of alumino-thermic composition, which was continually urged forward by a spring as its head burned away. Primary ignition of the portfire itself was by means of a cerium-steel "briquet."



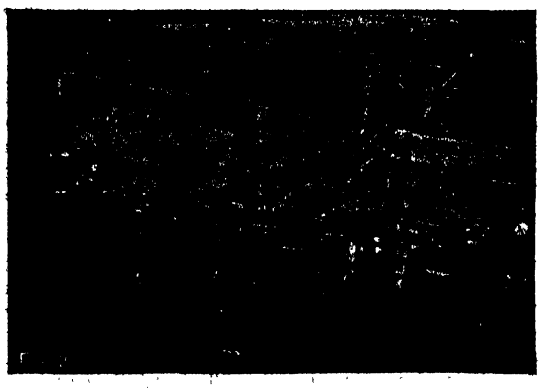


FIG. 1.

(*c*) The German service igniter (fig. 1), which was very ingeniously devised and was based on inertia. It was a double-walled cylinder attached to the nozzle-tube. The space between the inner and outer walls was filled with an alumino-thermic composition, open to the air at the top. Inside the hollow of the cylinder and in prolongation of the bore of the nozzle-tube were a piston, a spring, a striker-needle mounted on a pellet, and a cap with powder-relay. Between the cap and the striker-needle was a fixed disc of cardboard. On release the sudden impact of the jet on the piston compressed the spring and the striker against the cardboard disc, then after a moment the needle penetrated this disc, and the spring, decompressing itself, forced it on to the cap and so fired the powder relay that ignited the composition. The attachments which secured the striker, etc., in the bore of the cylinder were instantly burned through, and the jet, blowing out these obstructions, issued and was ignited by the burning composition as it emerged.

The types of flamethrower designed by the three belligerents were classified broadly as heavy, medium or semi-portable, and portable. Those of the heavy class, built for range, all required fixed installations; medium types were simply smaller editions of the heavy types, kept down in weight so as to be able to follow up an advance without undue difficulty; while the portable weapons were without exception designed for use in the course of the attack itself, and especially for the "mopping-up" of captured trenches and for securing the flanks of a line of trenches during "consolidation." In reality, therefore, there are only two types, the heavy and the light, and these are technically very different.

*Heavy Flamethrowers.*—Of the various types of heavy flamethrower which were evolved in the war, the British show both the best ranging power and also perhaps the greatest variety, this latter being due to the fact that, officially, they never passed beyond the experimental stage into that of a "service store."

The first model to be tried was that designed by an American, Joseph Menchen, which was put before the War Office in March 1915. This was a very large apparatus, several containers being coupled up in series to a single pipe and nozzle, the latter being aimed from under cover by means of power derived from a by-pass on the air bottle (a complication subsequently abandoned). The intention of the branch of the War Office concerned (which subsequently became the Trench Warfare Department of the Ministry of Munitions) was to employ the apparatus not in trenches, for which it was evidently too cumbrous, but to mount it in a large armoured vehicle of the caterpillar class. Such a vehicle was built, concurrently with the first tanks but on a larger scale so as to be able to carry a big supply of oil for the flamethrower, which in the Menchen design had a range of 100 yards. This idea of the flamethrower-tank was, however, allowed to drop owing to a variety of causes, of which the principal were the dislike of the British G.H.Q. in France for flamethrowers generally, and the concentration of caterpillar-building resources at home on the gun-carrying tank. Experiment proceeded therefore on heavy types intended for trench warfare, and greater lightness and simplicity than was possible with the Menchen design was aimed at. Later in 1915 the Department produced a heavy flamethrower "battery" which embodied many of the features of the Menchen, and some of those of the Hersent apparatus which had been evolved in France. This "battery" is typical of the normal heavy flame-thrower.

The "battery" (fig. 2) consisted of four vertical cylinders 16 in. in diameter and 48 in. high; on the top of each cylinder was a valve (controlled at first by a wheel and later by special mechanism) which was attached to a siphon tube in the interior of the container. The four valves were connected up in series by short lengths of flexible metallic tubing. The container communicated by a length of flexible tube with a rigid tube terminating in a nozzle; this discharge tube was mounted in the trench parapet behind a shield in such a way that the jet could be delivered in any direction and with any elevation. In the final container valve—*i.e.* that leading to the delivery piping—was mounted a trigger valve. On each container was strapped a gas bottle (compressed air, later nitrogen) containing 60 cub. ft. of gas compressed to 1,800 lb. per sq. inch. Between

this and the oil container were interposed a reducing valve (to reduce the storage pressure to a working pressure of 250 lb. per sq. in.) and a pressure gauge. Each oil container, when filled about three-quarters full (as was the usual practice), held 23 gal. and weighed 180 lb. filled. Ignition was at the nozzle by means of the electric device above mentioned. The range of this model was about 90 yd. actual throw. This apparatus, modified in details, was operated on one or two occasions in very unsuitable conditions during the battle of the Somme 1916, and was then rejected by G.H.Q.[1] But before experiment was abandoned two important alterations were made. (*a*) The valves between the separate containers were done away with, and the freer flow of oil thereby obtained enabled a "record" range of 134 yd. to be reached. (*b*) The "director tube" built into the parapet was replaced by a so-called "monitor," a lazy-tongs device carrying a short, universal-jointed, nozzle-tube, which was raised above the parapet only during firing, the whole installation at other times being below ground in a dugout. Other improvements were made to facilitate assembly and taking down in trench conditions. On one occasion a complete "battery" of four containers and monitor was taken down, removed, reassembled, filled and fired in slightly less than 15 minutes by ten men. The container unit was also lightened.

French heavy flamethrowers were substantially of the same character as the British model just described, but simpler. They did not range quite so well. Storage pressure was somewhat higher, working pressure slightly lower than in the British engines. The unit container was shorter and wider, and of lower capacity; the "battery" usually consisted of three containers placed one behind the other and connected by coupling-pipes at an acute angle to a single collector-tube which carried the nozzle. As above mentioned nozzle ignition and ground ignition were both used.

The German *Grof* (*grosser Flammenwerfer*) was similar in capacity to the British "battery" type, but otherwise resembled the French.

A heavy flamethrower of an entirely different type was the Livens, designed by Capt. Livens, R.E. In this the containers were, so to speak, elongated until they took the form of a single long 9-inch pipe stowed horizontally in a deep dugout or gallery. In the pipe worked a floating piston which separated the gas and the oil positively. Along this pipe, at intervals, were placed refilling tanks, so arranged that at the conclusion of each shoot the pipe-container could be refilled with oil very quickly by power supplied from the main reservoir of propellant gas. In the model here described three shoots could be made, each of 80 gal., in four minutes. The propellant gas, stored in the usual bottles, was admitted to a welded reservoir which was tested to 1,800 lb. per sq. inch. This equalizing reservoir gave a powerful and steady drive at the relatively high working pressure of 325 lb. per sq. inch. At the end of the container pipe was a "monitor" or rising discharger, arranged on the principle of a hydraulic ram, worked by the oil itself. This rose through a hole in the roof of the dug-out, delivered its shot, and sank automatically when the oil which supported it was drained off below.

*Portable Flamethrowers.*—These were used to a far greater extent in the World War than were the heavier types. In most cases the container with the gas bottle strapped to it was carried on the man's back, and the discharger tube with nozzle carried in his hand, the two being connected by the usual flexible pipe. The necessary lightness was obtained of course by the sacrifice of ranging power, both quantity of oil and working pressure being lower (3 gal., and 140–170 lb. per sq. in. respectively in the French "Schilt" types).

The general principles were similar to those of the heavy flamethrowers, except in the method of release. Whereas in the heavy types a single long-ranging shot of great power is fired in one blast, in the light type—or at least in those light types designed after the requirement had been realized—a succession of very short spurts is arranged for by a quick-acting trigger-valve of some sort. This enables the user to move hither and thither, driving back now one party of the enemy, now another, or clearing several dugouts in succession without reloading. In earlier French patterns ignition was by incendiary grenades after a shot of unignited oil, but the tactical usefulness of this weapon, even more than that of the heavy type, suffers by this limitation, and in all later French models nozzle-ignition is fitted. Of these the Schilt "No. 3 bis" may be taken as representative (fig. 3). Its outstanding characteristic is the power of delivering very many short shots without reloading. The "record" is no less than 103, but such a figure can only be obtained at the expense of range, and the usual practice was to use up one filling in about 8 or 10 shots with a range of rather less than 30 metres. The ignition device is the "tubular magazine" mentioned earlier and burns for 8–9 minutes. The dimensions are: container 2 cm. thick, 55 cm. high and 20 cm. in diameter, tested to 427 lb. per sq. in. with a capacity 3 gallons. The gas is at a storage pressure of 2,133 lb. per sq. in., which a reducing valve converts to a working pressure 171 lb. per sq. inch. The trigger valve has to be held down in operation and instantly springs up and closes the passage of oil if the operator is shot—an important point, as experience had shown in the case of the earlier small flamethrowers, which emptied themselves in a single shot. A tap is also fitted, at the origin of the flexible tube, which is turned on in going into action. The flexible tube is about 2 ft. long, and ½ in. in bore, the nozzle pipe also 2 ft. long with an orifice of $\frac{1}{12}$ inch. The total weight, full, is about 65 lb. Fig. 3 shows the apparatus in action. Like all French flamethrowers it was designed by Capt. Schilt of the Paris *sapeurs-pompiers*, who also organized the special flamethrower companies named after him.

FIG. 3.

The original German light *Flammenwerfer*, known as *Kleif*, was a 3-gallon engine which presents no particular point of interest. It was replaced by a smaller weapon known as *Wex*, which had a capacity of 2½ gal. and was fitted for successive shots. Both "*Kleif*" and "*Wex*" were operated by two men, one carrying the container knapsack-fashion while the other carried the discharge pipe and moved about as required.

The early British types known as the Norris, or Norris-Menchen, were of much the same general design as the Schilts; the first emptied themselves at one shot, the later ones had trigger valves. Another type, invented by Lt. Lawrence, R.E., and originally designed to throw either poison-gas or flame or both, was, after modification to convert it into a flamethrower pure and simple, found to possess a much longer range, as well as a better balance of the elements of the design than any existing model. Its range was no less than 45 yd., and it was capable of maintaining that range for some 15 to 18 shots from a single filling of 3 gallons. Safety was ensured by the use of inert gas and by the fact that if the operator lost control all valves automatically closed. This type was under manufacture in Russia in 1917 at the time of the Revolution. Experiments were also made in England with smaller models, some of which were used in the Zeebrugge landing in 1918. Finally, a flame projector was designed but never actually used, which acted in the same way as a land mine, *i.e.* it was buried and left to itself, inert, till the enemy in his advance stumbled upon a tripwire which set the machine in operation.

*Tactical Uses.*—Flamethrowers used in the World War were in all the three countries which employed them engineer weapons. In Great Britain those used on service were manned by a unit of the Special Brigade R.E. In France Capt. Schilt, the designer of the Schilt throwers in use, organized some seven companies of engineers known as *compagnies Schilt* for flamethrower work. In Germany it was the special province of a unit of pioneers which from small beginnings finally became the Guard Reserve Pioneer regiment, and lent its weapons and its men to the "assault battalions" as required. These battalions generally included in their attack formations a number of portable "Kleifs" or "Wexs." The G.R.P.R. also found heavy machines (two coupled) and personnel for shell-hole warfare and anti-tank defence.

In reviewing, even generally, their tactical work in the war, and estimating their future potentialities, it is obvious that a clear distinction must be drawn between the heavy and the light types. The intermediates were, and so far as can be seen will always be, an unnecessary type possessing the defects without the virtues of the others.

Too little use was made in the war of true heavy types, such as the British "battery" and "Livens," for any final judgment

[1] The available sets were handed over to Russia, a company of escaped Russian prisoners of war being formed and trained in England to handle them. No use was apparently made either of the apparatus or the trained men, owing to the Revolution.

to be passed on their usefulness. But it is evident that that usefulness will be confined to siege warfare, so far as ground installations are concerned. Quite apart from the necessity of burying the whole apparatus in shell-proof dugouts, the difficulty of supplying it with oil for constant use is considerable: eighty gallons of mixture with a specific gravity of .8—the contents of a Livens tube weigh 640 lb. without the transport receptacle, and three shots can be fired in four minutes. Stated in this way the problem is the same as that of supplying an 11-in. howitzer emplaced in the foremost trench. The load can be brought up in smaller units, it is true, whereas a shell cannot be subdivided for transport. But it is nine times as bulky, and continuous supply would be as difficult in the one case as in the other. Another consideration is the material itself—in some conditions of warfare petrol and oil may be more precious than iron and steel. Thirty "Livens" machines on one mile of front would consume about 1,000 gal. of petrol (neglecting the oil) per minute of actual continued activity. Fifty-five minutes of this activity on one mile of front would consume as much essence as the whole fleet of lorries belonging to the French Army consumed in a day during the winter of 1917–8. Evidently then the heavy flame projector if used at all will only be used in situations and tasks for which no more economical and handy weapon is available. The question is—do such situations exist? And the answer is evidently that, even if they do exist, they are not found on any considerable frontage at the same time. And so we find that the utility of the immobile heavy flamethrower is restricted to certain points and certain circumstances, such as may here and there be found (but not necessarily foreseen) in siege warfare. Any future that the heavy flame projector may possess in field warfare, or even in large-scale trench warfare, then, will depend on its being made mobile, *i.e.* on its being mounted in a tank.

The portable flamethrower, on the contrary, found many occasions of useful employment in varied conditions during the World War. Amongst its rôles were: surprise attack following a stealthy approach, to enable an infantry attack to debouch from trenches; "mopping-up," *i.e.* clearing a captured trench system of isolated but still dangerous parties of the enemy while the main attack presses on; blocking the flanks of a captured length of trench; forcing the surrender of enemy parties which have taken refuge in dugouts (perhaps the most frequent, if not the principal rôle in trench-warfare offensives); holding off close attack upon a party withdrawing, *e.g.* after a raid; engaging a strong point frontally while infantry work round the flanks. This catalogue shows the variety of functions which may be and have been carried out by small flamethrowers. It will be noticed that many of these rôles are by no means peculiar to trench warfare, and also that nearly all presuppose close coöperation with small bodies of infantry, the tactical units of the future. It is too much to say that the flamethrower is indispensable in the performance of the average battle task of modern infantry, but it is, on occasion, undeniably more useful than other close-range auxiliaries of the infantryman. Its main handicap is the difficulty of maintaining oil supply in an advance of great depth. This is serious, and may restrict it to employment in the methodical attack and defence of fortified regions. (C. F. A.)

**FLECKER, JAMES ELROY** (1884–1915), British poet, was born at Lewisham Nov. 5 1884, the son of the Rev. W. H. Flecker, D.D., afterwards headmaster of Dean Close school at Cheltenham. He was educated at Uppingham and Trinity College, Oxford, proceeding later to Caius College, Cambridge, where he studied oriental languages for two years before entering the consular service. He was sent to Constantinople in 1910 and to Beyrout in 1911. There he married a Greek lady. But his health failed early and he died at Davos Platz, Switz., Jan. 3 1915. His poetic output, though small, was choice, showing much affinity with the French Parnassien school, as well as with Swinburne and Francis Thompson. During his lifetime he published four small volumes of poetry; one more and two privately printed volumes appeared after his death, and his *Collected Poems*, with an introduction by J. C. Squire, were published in 1916. He also left two unpublished dramas, *Hassan* and *Don Juan*. A short satire, *The Last Generation* (1908), and a novel, *The King of Alsander* (1914), were his only important prose works.

**FLEMING, SIR SANDFORD** (1827–1915), Canadian engineer and publicist (*see* 10.494), died at Halifax, N.S., July 22 1915.

**FLINT, ROBERT** (1838–1910), Scottish divine and philosopher (*see* 10.521), died at Edinburgh Nov. 25 1910.

**FLORIDA** (*see* 10.540).—The pop. of the state in 1920 was 968,470 as compared with 752,619 in 1910, a gain of 215,851 or 28·7% for the decade. There were 17 cities with a pop. of over 5,000; those exceeding 10,000 with their proportional gain for the decade were:—

| | 1920 | 1910 | Increase % |
|---|---|---|---|
| Jacksonville | 91,558 | 57,699 | 58·7 |
| Tampa | 51,608 | 37,782 | 36·6 |
| Pensacola | 31,035 | 22,982 | 35·0 |
| Miami | 29,571 | 5,471 | 440·5 |
| Key West | 19,945 | 18,749 | 6·0 |
| St. Petersburg | 14,237 | 4,127 | 245·0 |

Despite a comparatively rapid growth of its cities and towns the pop. of the state was still predominantly rural. The urban pop. (those living in cities and towns of over 2,500 inhabitants) numbered 355,825 in 1920, 36·7% of the whole, as contrasted with 219,080 or 29·1% in 1910. This gave Florida the largest proportion of urban population of any southern state. During the winter months the population was each year largely augmented by thousands of tourists and winter residents. The E.-coast and Gulf-coast resorts were the chief objectives, but many of the inland towns and cities were beginning to attract visitors. In 1916 the Baptists were numerically the strongest denomination, with a membership of 131,107; the Methodists second, with 114,821; followed by the Roman Catholics, 24,650; Episcopalians, 10,399; Presbyterians, 10,170; and Congregationalists, 2,878.

*Industries and Commerce.*—Florida's most extensive industry is agriculture. According to figures of the Florida Experiment Station there were approximately 6,000,000 ac. of land in farms in 1920, not including open or fenced range lands. Of this, 1,700,000 ac. were in crops and 200,000 ac. of crop lands were idle; 180,000 ac. were in fruit; 1,120,000 ac. were in pasture; and 2,800,000 ac. in woodland. On approximately one-third of the cultivated acreage crops were produced by intertillage (the growing of two or more crops on the same land at one time) and by succession planting (where two or more crops follow each other on the same land during the year). The number of farms in Florida in 1910 was 50,016; in 1920, according to preliminary figures of the U.S. census, 54,006. Fruit was the most important crop. By the practical eradication of citrus canker, and the control of the white fly, through the vigorous campaign that has been waged against these enemies of citrus growth under the direction of the State Plant Board, the citrus industry has been greatly benefited and has prospered despite the fact that some of the groves in the more northern parts of the state have suffered by several severe winters. In 1920 the production of oranges was 8,500,000 boxes valued at $18,700,000, and of grape fruit 5,000,000 boxes valued at $10,000,000. In the sub-tropical part of the state pineapples, lemons, guavas, and avocadoes were grown profitably on a commercial scale. Other fruits were peaches, pears, bananas, grapes, figs, and limes. Other crops produced in Florida, with their 1920 yields and values were:—

| Crop | Quantity | Value |
|---|---|---|
| Indian corn (bus.) | 10,530,000 | $10,530,000 |
| Oats (bus.) | 1,020,000 | 612,000 |
| Hay (tons) | 132,000 | 2,508,000 |
| Wild hay (tons) | 20,000 | 300,000 |
| Peanuts (bus.) | 3,220,000 | 4,798,000 |
| Rice (bus.) | 72,000 | 126,000 |
| Irish potatoes (bus.) | 2,625,000 | 5,250,000 |
| Sweet potatoes (bus.) | 4,275,000 | 5,130,000 |
| Sorghum syrup (gal.) | 84,000 | 840,000 |
| Sugar-cane syrup (gal.) | 6,110,000 | 6,000,000 |
| Cowpeas (bus.) | 184,000 | 506,000 |
| Velvet beans (bus.) | 1,300,000 | 2,500,000 |
| Cotton (bales) | 18,000 | 1,530,000 |
| Tobacco (lb.) | 4,620,000 | 2,218,000 |
| Pecans (lb.) | 3,000,000 | 1,250,000 |

The encroachments of the boll weevil and the scarcity of farm labour, together with the unsettled condition of the cotton market, caused a falling off in the production of cotton during the decade 1910–20, and in many sections where cotton used to be raised it is no longer planted. The tobacco-growing section of western Florida produces profitably a shaded leaf, grown from Cuban and Sumatran seed, which is in great demand in cigar manufacturing. The pecan industry is comparatively new, most of the commercial groves having been planted since 1905. It is believed that in the northern part of

the state, the pecan crop soon may compete closely with the citrus crop of the southern part of the state. The open winters and light soil of Florida make many of its counties well adapted to the production of early vegetables for the northern markets. The industry is developing rapidly and the Florida producer can put vegetables on the northern markets earlier than any of his competitors. The chief obstacle in the way of further development of this industry is costly rates and inadequate railway freight service. The latest available figures on truck production, for the season of 1917–8, the trucking season being the winter, spring and early summer months, are given by the Florida Commissioner of Agriculture as follows:—

| Crops | Ac. | Crates | Value |
|---|---|---|---|
| Onions | 1,155 | 94,489 | $ 175,539 |
| Lettuce | 2,683 | 747,346 | 518,874 |
| Celery | 1,661 | 854,298 | 798,161 |
| Peppers | 8,039 | 845,213 | 1,363,264 |
| Irish potatoes | 38,596 | 4,552,465 | 4,403,361 |
| Cabbage | 10,253 | 1,032,379 | 1,358,633 |
| Tomatoes | 21,186 | 2,852,426 | 6,287,557 |
| Squashes | 596 | 82,543 | 124,716 |
| Egg-plant | 1,616 | 358,737 | 596,336 |
| Cucumbers | 2,497 | 350,516 | 497,615 |
| Watermelons (cars) | 7,558 | 2,773 | 494,636 |
| Beets | 380 | 73,571 | 105,391 |
| String Beans | 8,006 | 1,360,136 | 1,933,578 |

In Florida much attention is paid to stock-raising. During the decade 1910–20 there has been a consistent grading up of both beef and dairy herds. Especially is this true of dairy herds, the average value of milch cows being more than five times as much in 1921 as in 1910. The live stock in Jan. 1920 was: horses, 60,000 valued at $8,400,000; mules, 40,000 valued at $7,840,000; milch cows, 156,000 valued at $11,232,000; cattle other than milch cows, 945,000 valued at $25,798,000; sheep 95,000 valued at $494,000; swine, 1,588,000 valued at $20,644,000; a total for all stock of 2,884,000 head with a total valuation of $74,408,000.

In 1916 the total value of minerals produced in the state was $5,859,821, the more important of which were phosphates, lime, limestone, brick, tile, and fuller's earth, of which latter Florida produced in that year more than three-fourths of the entire output of the United States. Phosphate production according to the last available figures in the Ninth Annual Report of the Florida Geological Survey was, in long tons:—

| | 1913 | 1916 |
|---|---|---|
| Pebble | | |
| Exported | 887,398 | 172,427 |
| For use in U.S. | 1,168,084 | 1,296,331 |
| Total | 2,055,482 | 1,468,758 |
| Hard Rock | | |
| Exported | 476,898 | 28,045 |
| For use in U.S. | 12,896 | 19,042 |
| Total | 489,794 | 47,087 |
| Grand Total | 2,545,276 | 1,515,845 |

The total mineral production for 1919 was put by the State Geological Survey at a valuation of $10,603,620.

In 1916 the output of lumber was 1,425,000,000 ft., in 1918 950,000,000 ft. In 1918 Florida stood second in the production of cypress with a total of 85,376,000 ft., and sixth in production of yellow pine with a total of 765,912,000 ft. The high prices of lumber during most of the decade 1910–20 made this industry highly profitable. Naval stores are produced from the pine forests, where the sap of the trees is collected and distilled, yielding turpentine and rosin. In 1905 Florida's naval stores were valued at $9,901,905. In 1917 there was a production of 8,824,295 gal. of turpentine valued at $13,018,447, and of 414,226 bar. of rosin valued at $3,260,107, or a total valuation for naval stores of $16,278,554. The manufacture of cigars and, to a much smaller extent, cigarettes is carried on chiefly in Tampa and Key West. In 1905 the gross value of production was $16,764,276. In 1917 Florida produced 469,301,042 cigars valued at $30,127,941 and 7,800,000 cigarettes valued at $154,000. A rapidly growing Florida manufacture is the production of commercial fertilizers, large amounts of phosphate mined within the state being used for this purpose.

*History.*—The outbreak of the World War in 1914 interrupted two of Florida's more important exports to Europe, naval stores and phosphates, thus creating a temporary business depression. In the naval stores industry the recovery was comparatively rapid, owing to the high prices of and increased domestic demand for the products during the period of the war, with the exception of its early months. The phosphate industry was more seriously affected, as Germany had been a large purchaser of Florida phosphates. Many of the Florida phosphate mines closed down, to resume operation only after the signing of the Armistice.

The political history of the state during the decade 1910–20 was uneventful. The question of prohibition played a large part in state politics until the ratification of the Eighteenth (Prohibition) Amendment to the Federal Constitution by the Florida Legislature Dec. 14 1918. Since 1876 Florida has been uniformly democratic and, except in 1916, when a contested primary election in the democratic party resulted in the nomination of Sidney J. Catts as a prohibitionist and in his election as governor, all of the state's executives have been democrats. The governors after 1910 were: Albert W. Gilchrist, 1909–13; Park Trammell, 1913–17; Sidney J. Catts, 1917–21; and Cary A. Hardee from 1921.

A proposed constitutional amendment to effect reapportionment was passed by the Legislature in 1921, to become operative if voted on favourably in Nov. 1922. This measure would give more adequate representation to parts of Florida that have increased greatly in population. Several new counties have been created since 1910. From territory taken from De Soto co. the four new counties of Glades, Hardee, Highlands, and Charlotte have been formed; Lafayette co. has been divided, the southern part to be known as Dixie; Hillsborough's western part has become Pinellas co.; Flagler co. has been formed from the northern territory of Volusia and the southern part of St. John's; parts of Palm Beach and Dade have been joined to create Broward; the western part of Walton and eastern part of Santa Rosa have been combined under the name of Okaloosa; part of Bradford has been made into Union; part of Manatee into Sarasota; parts of Washington and Walton have become Bay; parts of Osceola, St. Lucie and Palm Beach are now known as Okeechobee; and from the northern part of Orange Seminole has been created.

Florida furnished 42,301 soldiers, sailors and marines for the World War and the casualties among them were 1,171, including 467 dead. The state's subscriptions to the Liberty and Victory loans were: First Liberty Loan, $5,271,000; Second $8,611,000; Third $18,053,900; Fourth $27,538,100; Victory Loan, $17,918,100—the total for the five being $77,392,100. (J. M. L.)

**FLYING CORPS.**—Aviation, as a military service, took new organized forms during the World War, and its development in this respect is dealt with in the following pages; the art of flying itself is treated under AERONAUTICS. At the present time, the general name of "Air Force" has come into official use to cover the different forms of organized military and naval aviation, but earlier in the World War the usual term was "Flying Corps." The development of the British air forces will be treated here first.

I. MILITARY AVIATION.—The first official appearance of any form of aircraft as part of the British army (for the navy, see later) was in 1878, when a Royal Engineers balloon equipment store was established at Woolwich Arsenal. In the following years, besides practice in manœuvres (both field and siege), experimental work was carried on at Woolwich, and later at Chatham, in the direction of getting a better gas, a more suitable fabric for the envelope, and more adequate means of filling the balloons than existed at the time. The question of transport for balloons was also carefully gone into. As a result of this decision a small factory, depot and school of instruction were started at Chatham in 1883. In 1884 it was decided to include a balloon detachment among the R.E. units mobilized for service in Bechuanaland and in the following year a similar detachment was sent on service in the Soudan. In 1890 the balloon section was recognized as an individual unit of the R.E.; the factory and the school were moved to Aldershot, the depot remaining at Chatham. At this time its strength was 33 all ranks.

Up to the beginning of the S. African War of 1899–1902 the organization of the balloon section remained the same. On the outbreak of that war it was decided to send balloons to S. Africa, and three sections in all went out.

In 1902 the first British airship, "Nulli Secundus," was commenced at the balloon factory, which also continued research into man-lifting kites, photography, signalling between ground and balloons, petrol motors, elongated balloons and mechanical hauling apparatus. In 1905 the balloon factory was moved to S. Farnborough, and experiments were carried out at Gibraltar with a view to seeing to what extent balloons could be utilized in spotting submarines and mines.

The growing importance of aeronautics was signalized in Oct. 1908 by the appointment of an appropriate standing sub-committee of the Committee of Imperial Defence. This committee reported in Jan. 1909 in favour of a small expenditure being authorised for building a rigid airship for the navy, and of

perimenting on non-dirigibles for the army, but recommended discontinuance by the balloon establishment of its experiments with aeroplanes for progress in which it would be better to rely on private enterprise. In April 1909 the "Advisory Committee for Aeronautics" was appointed under the presidency of Lord Rayleigh to advise on questions relating to the science of aeronautics, to arrange when necessary for experimental work at the National Physical Laboratory and generally to advance the practical application of the science.

In Oct. 1909 the balloon factory and balloon school at S. Farnborough, which had hitherto been under one control, were separated, a commandant of the school and superintendent of the factory being appointed. The next step of any importance was the formation in 1911 of the Air Battalion R.E. This Air Battalion absorbed the existing elements of the balloon section, and consisted of a headquarters and two companies, No. 1 (airship and kite) and No. 2 (aeroplane), the latter being the first heavier-than-air unit to form part of the British army. The expansion of the Air Battalion on mobilization was provided for by the selection of officers of the regular army to form the Air Battalion Reserve.

At this time there were less than 12 efficient aeroplanes and two small airships for both naval and military requirements, while France had 250 aeroplanes and several airships, and Germany had 20 to 30 military aeroplanes and about 20 airships. Towards the end of 1911, therefore, it was realized that the rapid development of aeronautics abroad rendered necessary further study of the possibilities of aviation in its relation to Imperial Defence, and on Nov. 18 1911 the Prime Minister requested an air sub-committee of the Committee of the Imperial Defence to consider the question. This sub-committee delegated to a technical sub-committee the task of drawing up a scheme. Its main recommendations, accepted by the air sub-committee and finally by the Committee of Imperial Defence and the Government, were as follows:—

(*a*) That the British air service should be regarded as one, and called the "Flying Corps." This corps to provide the personnel necessary for naval and military wings, for the Central Flying School and for a Flying Corps Reserve. (*b*) That the Central Flying School should be established on Salisbury Plain at the joint expense of the Admiralty and the War Office, but administered by the latter. (*c*) That after graduating as pilots at the Central Flying School officers should go for further instruction to the Naval Flying School at Eastchurch, or to a military squadron as the case might be, or else pass into the reserve of the Flying Corps.

The technical sub-committee also recommended that the technical requirements for both wings of the Flying Corps should be provided by the army aircraft factory, which should henceforth be known as the "Aircraft Factory." This aircraft factory, which was the direct descendant of the balloon factory, and out of which was eventually evolved the Royal Aircraft Establishment, should be charged with the higher training of mechanics for the Flying Corps, the repair of engines and machines, research and experiment.

Further, it was recommended that in order to secure close collaboration between the naval and military wings, the Central Flying School, the aircraft factory and the Advisory Committee on Aeronautics, a permanent air sub-committee of the Committee of Imperial Defence should be constituted under the chairmanship of the Under-Secretary of State for War, and having as its members the senior officers of the corps and the factory, with War Office and Admiralty representatives.

With regard to the supply of personnel for the Flying Corps, the technical sub-committee recommended that its officers should be exclusively graduates of the Central Flying School, the supply being from either the navy or the army or by direct entry from civil life. After graduating, officers should serve continuously for four years in the Flying Corps with the naval wing, military wing, on the permanent staff of the Central Flying School or the Flying Corps Reserve. The Flying Corps Reserve to consist of personnel only, and to be divided into two classes:—(*a*) those who were required to keep themselves in flying practice; (*b*) others not under this obligation. The first were to receive a retaining fee.

It was estimated that the navy would require 40 officers trained as pilots per annum. As regards the military wing, the seven aeroplane squadrons considered necessary for the Expeditionary Force would require a total of 182 officer pilots and 182 N.C.O. pilots. Assuming four years of active flying work as the limit for the average individual and adding 25% for casualties, failures, etc., the number eventually to be passed through the Central Flying School per annum would be about 164. In addition it was recommended that 15 civilians should be trained annually as pilots and passed into the Reserve.

With regard to the naval wing of the R.F.C., the technical sub-committee recommended that after being at the Central Flying School officers should then pass on to Eastchurch for further training in the special forms of naval aeronautics. It was, incidentally, further recommended that in view of the great cost involved it was not considered advisable to build rigid airships.

As regards the military wing of the Flying Corps, it was recommended that it should comprise all branches of military aeronautics, including aeroplanes, airships and kites, and should accordingly absorb the existing Air Battalion of the R.E. For an expeditionary force of six divisions and one cavalry division it was estimated that one headquarters, seven aeroplane squadrons of 12 machines each, one airship and kite squadron and one line-of-communication workshop would be required. The organization of a squadron was to be headquarters (seven officers, 17 other ranks), and three flights of four machines each (each flight consisting of four officers and 46 other ranks).

On May 13 1912 the R.F.C. was inaugurated. The programme adopted for its development, apart from a few alterations in detail, was on the lines recommended by the technical sub-committee. The first two squadrons to be formed of the military wing were Nos. 1 and 3. The former was No. 1 (Airship) Co. of the Air Battalion. It had on charge two airships, "Beta" and "Gamma," the "Delta," "Zeta" and "Eta" being added subsequently, as well as man-lifting kites and free balloons for training. No. 3 Squadron was formed from No. 2 (Aeroplane) Co. of the Air Battalion. Later in 1912 Nos. 2 and 4 companies were formed,[1] and in June the Central Flying School opened at Upavon. Wing headquarters and the line-of-communication R.F.C. workshop (later known as the Flying Depot and then as the Aircraft Park) were located at S. Farnborough. The naval airship service, which had been constituted in connexion with naval airships experiments in 1909 and disbanded in 1912, was re-raised and attached to No. 1 Airship Squadron.

Considerable progress was made in 1913 both in organization and otherwise, and at the end of the year 92 officers were serving with the military wing, 25 officers in the reserve and 22 in the special reserve. Other ranks totalled 999. The approximate strength of the naval wing was 125 officers, including warrant officers, and 500 men. The annual report of the Central Flying School showed that 28 naval and 69 military officers had passed out, and 14 N.C.O.'s. had obtained 2nd-class pilot certificates. Experiments with machine-guns mounted on aeroplanes were made during 1913 by the military wing, and the aeroplane inspection department was formed at S. Farnborough.

A sub-committee of the Committee of Imperial Defence, appointed in 1913 to consider the control of aircraft in peace and war, recommended that the Aerial Navigation Act of 1911 should be amended so as to give power to requisition aircraft in time of war, and that the commandant of the Central Flying School should keep a register of privately owned aircraft. The Aerial Navigation Act of Feb. 1913 amended the previous Act in accordance with these recommendations. It was also laid down that one of the conditions in qualifying for the Royal Aero Club certificate should be an obligation to serve in any branch of the R.F.C. in time of war.

In Sept. 1913 a directorate of military aeronautics was formed at the War Office. It was to be an entirely self-contained department, and its head had direct access to the Secretary of State. It was charged with the general administration of the Army Air Service, and was made responsible for all work in connexion with the personnel and equipment of the Central Flying School, the military wing and the Royal Aircraft Factory.

In Jan. 1914 it was decided that in war each squadron should have 12 active and three reserve aeroplanes, and the flying depot 21 reserve machines. In peace, squadrons were to have 21 aeroplanes and the flying depot 28. The airship material of No. 1 Squadron was handed over to the Admiralty, who became responsible for all lighter-than-air craft, and the squadron was re-formed as an aeroplane squadron.

[1] No. 5 was formed in 1915 and Nos. 6 and 7 in the first half of 1914.

*Development during the World War.*—The directorate of military aeronautics had, prior to the outbreak of war in Aug. 1914, drawn up a mobilization scheme providing for the dispatch overseas of 4 squadrons and the retention in England of 2 squadrons. The register of civilian pilots and privately owned machines had also been drawn up. All the existing squadrons were short of pilots, though nearly up to establishment in N.C.O.'s and men. The Central Flying School had been formed on a scale calculated gradually to build up the establishment of the naval and military wings that had been laid down, and was not capable of meeting at short notice the requirements that arose out of the emergency. Even the mobilization of four squadrons, therefore, was rather more than the existing resources of machines and pilots justified, and it became necessary to draw upon the Reserve and the Central Flying School.

On Aug. 3, when mobilization commenced, Maj.-Gen. David Henderson, director of military aeronautics at the War Office, was appointed general officer commanding the R.F.C., with the Expeditionary Force, and Maj. W. S. Brancker took over the War Office work as assistant director.

On Aug. 13 and 15, Nos. 2, 3, 4, and 5 Squadrons (less one flight of No. 4 left behind for Home Defence), flew from Dover to Amiens, followed by R.F.C. headquarters, the mechanics and transport of the squadrons, and the Aircraft Park, proceeding by boat and train. The Park was established at Amiens.[1]

The three main problems confronting the military aeronautics directorate at the War Office, after the departure of the Expeditionary Force, were (*a*) the training of pilots, (*b*) provision of skilled other ranks, (*c*) manufacture of aeroplanes and engines.

With regard to (*c*), coördination between the military aeronautics directorate and the Air Department of the Admiralty had hitherto been regulated by the air committee of the Committee of Imperial Defence; but on the outbreak of war the other preoccupations of its members led to a complete cessation of its functions and no controlling influence remained to balance the claims of the two wings.

With regard to (*a*) and (*b*), the existing organization provided for no expansions on the scale to be expected in the near future, and, with the exception of the Central Flying School, which had already been seriously depleted in both personnel and equipment, Farnborough was the only station in commission. No. 1 (Reserve) Aeroplane Squadron was formed at Farnborough and undertook the training of pilots. The number of mechanics was short, and skilled civilians were enlisted direct into the R.F.C. At the end of Sept. 1914 some pilots were sent home from France in order to reënforce the instructional resources at home, the demand for the replacement of wastage and for forming new squadrons promising to become heavy in the near future. The policy of expansion adopted was for the formation of as many reserve squadrons as the personnel permitted, and for each reserve squadron, in addition to training pilots *ab initio*, to be responsible for producing the nucleus of a service squadron.

By Oct. 1914 the scheme for the organization of the new armies had been drawn up by the War Office, and since experience in the field had made one artillery observation squadron per division a basis for estimating requirements, with, in addition, two or three fighting and reconnaissance squadrons per corps, it thus early became apparent that eventually at least 60 service squadrons would be required by the B.E.F. The question of long-distance bombing raids into Germany was not overlooked, but the urgency of the army's needs for coöperating units was such that their provision was for the time of primary importance and detailed consideration of an aerial offensive was postponed.

With the gradual increase in the number of units both at home and in the field, the need for decentralization became apparent, and led to the adoption of the "Wing" as an intermediate organization between the squadron and headquarters. Further, it was found in France that the tactical employment of aircraft suffered through their being controlled directly by G.H.Q. instead of being allotted permanently to subordinate commands. Accordingly, in Nov. 1914 wings were formed, and this reorganization of the R.F.C. (headquarters and squadrons) in the field synchronized with that of the higher army commands, the 1st Wing being allotted to the I. Army, and the 2nd Wing to the II. Army. It was laid down at the time that wings would be allotted to certain areas and would coöperate with units in that area. Special missions and strategical reconnaissances would be ordered by R.F.C. headquarters.

At home in the meantime the formation of No. 1 and No. 7 Squadrons (temporarily held up in order that all efforts might be concentrated on preparing No. 6 Squadron for overseas) was being proceeded with, the two squadrons being moved a little later to Netheravon, where a school had been started as an annex to the Central Flying School. The formation of other squadrons and reserve squadrons soon followed.

In France, during the opening months of 1915, the scope of R.F.C. activities rapidly extended, and the demands made on it for bombing, photography, message-dropping and artillery observation increased. Accordingly, a 3rd Wing was formed (March 1) and the number of squadrons in each wing was increased to three, a decision that led to the formation, in France, of No. 16 Squadron and the dispatch from England of Nos. 1, 7 and 8 Squadrons (March–April 1915). These increases necessitated a corresponding extension to the Aircraft Park. In Jan. 1915, an establishment of 50 squadrons was sanctioned. At the end of July a programme of development was drafted providing for the raising of 30 service squadrons and 10 reserve squadrons by Jan. 1 1916, and another 30 service squadrons with five reserve squadrons Dec. 1 1916. This development programme was based essentially upon what were considered the army's requirements in aircraft, the scale adopted being one squadron per corps for artillery observation and photography, one squadron for each army and one squadron for G.H.Q.

By this time aerial fighting had become general, and aircraft were armed so as to enable reconnaissance and artillery observation machines to protect themselves. After some experience it became evident that pure fighting machines would be required and that upon their ascendency over the enemy would depend command of the air and consequently the freedom from hostile interference so necessary for artillery machines to function efficiently. The machine that proved itself to have the last word in aerial combat was the fast, easily manœuvred fighting scout, which though designed for scouting ultimately developed into the modern fighting machine.

It was not, however, until early in 1916 that the policy of having scout squadrons was generally adopted,[2] the practice up to then having been to allot a few scouts to each squadron. Thus it was that at the time of the drafting of the 1915 programme the two-seater machine largely predominated.

In Aug. 1915, it was decided that the increase in the number of wings (the 6th Wing being now formed, and the 7th and 8th following in Nov.) demanded the institution of a higher intermediate formation, and in Sept. the brigade organization was adopted under this. Each brigade, commanded by a brigadier-general, was to consist of three wings and one Aircraft Park—the R.F.C. then in the field forming the 1st Brigade. The 2nd Brigade comprised the 4th, 5th and 6th Wings and the independent stations of Montrose and Brooklands. Under the Administrative Wing were placed the units at Farnborough and Northolt. A school of aerial gunnery was also opened at Dover (subsequently moved to Hythe) and the Aircraft Park organization was recast.

A school and officers' depot (subsequently known as the School of Military Aeronautics) was started in Nov. at Reading where officers joining the R.F.C. could be put through a course in engines, rigging, artillery coöperation, map reading, signalling, etc., before joining a reserve squadron for instruction in flying. A wireless telegraphy school was also formed at Brooklands.

Towards the end of 1915 it was decided to increase the strength of the R.F.C. in France so as to have one brigade or two wings with each army, and in addition to have one or two wings with G.H.Q. One of the wings in each brigade to be entrusted with close reconnaissance, photography and artillery work with corps and divisions, the strength of the wing being calculated at one squadron per corps, whilst the other wing would be available as required by the army commander for bombing, reconnaissance and patrol operation. This involved an establishment for the R.F.C. of 70 service squadrons and 20 reserve squadrons, which besides training pilots functioned as draft-producing units.

At the end of Jan. 1916, the brigade organization took definite shape in France, with the 1st, 2nd and 3rd units as "corps wings" and the 10th, 11th and 12th Wings as "army wings."

The question of home defence against aerial attack now became of primary importance. Up to Jan. 1916, a certain number of aeroplanes and pilots had been allotted to Home Defence, but on the War Office taking over the responsibility for anti-aircraft defence from the Admiralty in Feb. 1916, a definite Home Defence organization was adopted. At first some 25 B.E.C.2. aeroplanes were allotted to the defence of London, but were scattered about in small detachments and placed under officers commanding various reserve squadrons. As this was found unsatisfactory, all the detachments were placed under a single officer, whose headquarters were at Hounslow. As further development became necessary certain squadrons were converted into Home Defence Squadrons. In April a new Home Defence Squadron was constituted out of various detachments employed on Home Defence duties, and in June the Home Defence wing was formed to include all Home Defence units. This wing was attached to G.H.Q. Great Britain for operations. The two brigades at home were merged into one, this brigade being known as the 6th Brigade and later as the Training Brigade. It was

[1] On Oct. 7 eight machines of No. 6 Squadron flew to Bruges to take part in the operations of the 7th Division. By the 16th of the month, however, this squadron had withdrawn S. and had come under the orders of R.F.C. headquarters.

[2] No. 24 Squadron with De Haviland Scouts was the first of this type to go overseas on Feb. 6 1916.

also decided to raise the number of aeroplanes in each squadron from 12 to 18. This increase was to a large extent due to improvements in wireless telegraphy which enabled a larger number of machines to work on a given front. Subsequently, Fighter Reconnaissance (Army) Squadrons were raised to 24 machines per squadron.

It may be interesting here to examine the factors that tended to influence the policy that governed development as the war went on. It was out of events in France that these governing factors arose, and the requirements formulated by R.F.C. headquarters set the standard which those at home strove to reach. The scale that was adopted in the summer of 1915 provided for one squadron per corps for artillery observation, close reconnaissance, and photography; one squadron for each army headquarters and one squadron (to be later increased to two) for G.H.Q. for extended reconnaissance and special missions. The War Office accordingly committed itself at the time to providing 27 squadrons by the end of March 1916, but events in the field led to a request that this number should be increased by two artillery observation, one long-distance reconnaissance squadron and two fighting squadrons (one of single-seater machines and one of two-seaters). In June 1916, a revised schedule of anticipated requirements for the spring of 1917 was prepared, based upon the increase of the B.E.F. to five armies of four corps each and the growing importance of aerial fighting. This scheme, which provided for 66 squadrons (including 23 artillery and 20 fighter squadrons, with five night-flying squadrons and later 10 long-distance bombers, as well as two medium-distance bombers and four fighter squadrons under G.H.Q.), marked the growing importance of the fighter, a conception of an offensive into the enemy's country by means of long-distance bombers, and a break-away from the idea that close coöperation with other fighting forces was the beginning and the end of aerial operations.

By the middle of Nov., however, aerial fighting had increased still more, and the vital importance of the constant struggle for air supremacy had been so often emphasized that 20 fighting squadrons supplementary to the above programme were asked for. This meant a proportion of two fighting to one artillery squadron, in place of the parity in numbers of the two types previously accepted as a basis. So vital a question did the supply of fighters appear at the time that it was urged that, failing the 20, at least 10 extra squadrons should be provided, even at the expense of delaying the bombing and night squadrons. The situation in France in June 1917 showed that there was a total of 52 squadrons of different types. In addition to raising new squadrons, existing squadrons had to be equipped with more modern machines. It was, therefore, impossible for the War Office to promise that more than 73 squadrons would be in France by the end of 1917, including the five R.N.A.S. units.

In June 1917, the Air Board drew up a scheme providing for the expansion of the R.F.C. to 200 service squadrons and 200 training squadrons. Further evidence of the growing realization of the value of the aerial offensive is afforded by the fact that this proposal embodied (in addition to fighter squadrons) the raising of, at first, 40 bombing squadrons (DH9 and larger machines) to be organized into wings of five squadrons each, the wings to be grouped into four brigades. G.H.Q. France were accordingly asked to be ready for 40 squadrons in addition to 86 already expected to be ready by Aug. 1918. In Nov. 1917, the 1918 programme was drafted as follows:—

40 squad. single-seater fighter.
15 squad. single-seater fighter for ground fighting.
15 squad. two-seater fighter reconnaissance.
1 squad. long-distance 2-seater for reconnaissance and photography.
10 squad. short-distance day-bombers.
10 squad. short-distance night-bombers.
21 squad. for corps work.
1 squad. long-distance machine carrying Q.F. gun.

In addition, for the Bombing Brigades:—

25 squad. day-bombers.
20 squad. night-bombers.
20 squad. two- or three-seater long-distance fighters.
1 squad. long-distance machine with Q.F. gun.

This programme for 179 squadrons involved the supply of 2,400 machines for armies and 1,028 for the bombing brigades.

Finally, in Feb. 1918, 240 squadrons (in addition to training units) was accepted as the goal to be reached, 179 being for France and Italy, 40 for other theatres, and 21 in reserve.

Meanwhile, at the end of 1916 the home organization included:—(1) The Administrative Wing, Farnborough; (2) the Training Brigade of 9 wings, totalling 21 service squadrons and 43 reserve squadrons; (3) the Home Defence Wing, comprising 11 service squadrons and one depot squadron for the training of night pilots; (4) the Kite Balloon Training Wing, including a training depot, an inspection branch and two schools of instruction. The following training centres and schools had been formed, in addition to numerous reserve squadrons:—(1) Recruit Training Centre, Halton Camp; (2) School for Wireless Operators, S. Farnborough; (3) Balloon Training Wing, Roehampton; (4) No. 1 Balloon School, Larkhill; (5) No. 1 School of Military Aeronautics, Reading (including Equipment Officers' School and the School of Technical Training for other ranks); (6) No. 2 School of Military Aeronautics, Oxford; (7) Cadet Wing, Denham; (8) School of Aerial Gunnery, Hythe; (9) Central Flying School, Upavon; (10) Wireless and Observers' School, Brooklands; (11) Scottish School of Fitters, Edinburgh.

In Nov. 1916, with a view to meeting the deficiency in the supply of skilled men, arrangements were made to place about 400 men continuously under instruction at various polytechnic institutes throughout the country. During 1917 further expansion of the Home Defence service took place. A Northern Home Defence Wing was formed with headquarters at York and the Home Defence Wing became the Home Defence Group, which, as other wings were formed, subsequently became the 6th Brigade, and by 1918 had become responsible for the aerial defence of England and the South of Scotland, coöperation of coastal batteries, and the training of night-fighting pilots and night-bombing pilots for France. Other developments at home during 1917 included the formation of aircraft depots which were transferred from the Army Ordnance Department to the R.F.C., principally for the supply of spares. Acceptance parks were also formed the duties of which were to receive aircraft from the manufacturers, to erect, test and finally issue them to units or dispatch them overseas. The creation of a Department of Production under the Ministry of Munitions placed on a more satisfactory basis the supply of equipment for the R.F.C. The number of training units had increased to such an extent that it was found necessary to form them into groups (southern, northern, eastern, western). These groups became, shortly, brigades (the old training brigade then becoming the division), and the standard training unit, the reserve squadron, was renamed "training squadron."

For theatres of war other than France, separate arrangements were made from time to time for providing for the requirements in Egypt, E. Africa, Mesopotamia, Salonika, and Palestine.

II. NAVAL AVIATION.—The British Admiralty's first practical steps in aeronautics were taken in June 1908, when as a result of the Committee of Imperial Defence recommendations, it was decided to build a rigid airship. This ship, known as No. 1 naval airship (the "Mayfly"), was completed in May 1911, but was wrecked in the following September. This experience discouraged further attempts until Feb. 1911, when two civilian pilots offered their services free, with two machines, for the instruction of four naval officers as aeroplane pilots. Four naval officers were accordingly selected out of some 200 volunteers to undergo a six-months' course of instruction on the Royal Aero Club ground at Eastchurch. At the end of the year, land adjacent to the Royal Aero Club ground at Eastchurch was purchased by the Admiralty, and a naval flying school was formed there, four officers having in the meantime qualified as pilots. Thereafter, pupils were trained continuously at the school both before and during the World War. Apart from being used for training purposes, Eastchurch was the scene during 1911 and 1912 of many interesting experiments in the application of aircraft to naval uses. On the formation of the R.F.C., it was decided to form an Air Department at the Admiralty, this Department actually coming into being in Sept. 1912. By June 1913, the total number of aeroplanes and seaplanes in possession of the Naval Air Service were 37, and by October, 61 were in commission with three airships.

In Aug. 1913, the Admiralty decided to establish air stations at various points along the coast. An "Inspecting Captain of Aircraft" was placed in general charge, under instructions from the Director of the Air Department of the Admiralty. He was also responsible to the commander-in-chief home fleets regarding all matters concerning aircraft with ships afloat.

In June 1914, the increasing importance of the naval wing R.F.C. led to a reorganization of the service, and the R.N.A.S. came into being. It comprised the Air Department, Admiralty; the Central Air Office, Sheerness; the Royal Naval Flying School, Eastchurch; the Royal Naval Air Stations and all seaplanes, aeroplanes, airships, seaplane ships, balloons, kites and other types of aircraft that might from time to time be employed for naval purposes. Regulations were drawn up for the entry of officers as probationary flight sub-lieutenants direct from civil life and special designations were instituted for the various commissioned ranks in the flying branch.

With regard to airships, which by this time had passed entirely under Admiralty control, in the early part of 1913 German activity with rigid airships of the Zeppelin type led to a reconsideration of the question as to whether similar aircraft should be constructed for the British navy, and it was decided to arrange

for the construction of two rigid and six non-rigid airships. In June 1913 orders were accordingly placed for one Parseval in Germany, two Parsevals with Vickers, one Forlanini in Italy and two others of this type with Messrs. Armstrong. A contract for one rigid airship was signed with Messrs. Vickers in March 1914. But on the outbreak of the World War delivery of the airships building in Germany and in Italy became impossible, and the British firms could not complete the airships they had begun. Work ceased on the rigid airship in the early stages of construction, but was resumed during the war, and on completion this airship became known as Naval Airship R9.

It had been decided at the end of 1913 that the Admiralty should take over all airships and airship equipment from the army. Accordingly, on Jan. 1 1914 the naval and military airship sections were amalgamated at Farnborough, and the navy took over control of all airship administration.

*The War Period.*—At the outbreak of the World War the stations on the organized east coast system of aerial patrol were as follows:—Eastchurch, Isle of Grain with advanced bases at Westgate and Clacton, Felixstowe, Yarmouth, Immingham, Calshot, Dundee, Cromarty and Fort Grange. There was also the airship station at Kingsnorth. Patrols were organized between the Humber and the Thames estuary, and a cross-Channel seaplane and airship patrol was started between the Isle of Grain and Ostend, a temporary base for seaplanes being established there. The Channel seaplane patrol was discontinued when the enemy advanced to Ostend. An additional base was established at Skegness, and for a short time, until Aug. 12, the naval machines at Eastchurch were reënforced by machines from No. 4 Squadron R.F.C. The Admiralty acquired as seaplane-carriers the "Engadine," the "Riveria" and the "Empress," structural alterations being necessary before the ships could be used for the purpose. The necessity for aircraft to coöperate with the Grand Fleet led to the establishment of a base for seaplanes and aeroplanes at Scapa Flow, a seaplane-carrier, the "Campania," being later commissioned to convey machines with the fleet when it proceeded to sea.

The first Naval Air Service aeroplane unit to proceed overseas was formed at Eastchurch, and went to Ostend on Aug. 27 1914 to coöperate with the naval division at Antwerp. In order to protect the United Kingdom against German airship raids, an aircraft and seaplane base was established at Dunkirk.

In the meantime the organization of the R.N.A.S. at home underwent rapid development, both in the matter of the training of pilots and the construction and design of machines. On Sept. 3 1914, the R.N.A.S. assumed responsibility for the defence of the United Kingdom against hostile aircraft attacks, and a special anti-aircraft section was formed in the Air Department. The coast patrols were continued both by seaplanes and by airships, an additional station for these patrols being opened at Dover.

In 1915 squadrons and wings were formed and sent overseas to Dunkirk and the Dardanelles. A detachment of three seaplanes proceeded to E. Africa and subsequently to Mesopotamia. Towards the end of Feb. 1915 the naval squadron at Dunkirk was relieved by No. 1 Naval Squadron, which had been forming at Gosport, and proceeded to the Dardanelles as No. 3 Wing. Later the 2nd Wing from Eastchurch also proceeded to the Dardanelles where, moreover, were sent the seaplane-carriers "Ark Royal" and "Ben-my-chree." In the early part of Sept. 1915 the R.N.A.S. units at Dunkirk and Dover were amalgamated into the 1st Wing under the command of the senior Air Service officer at Dover. During the year a small unit of seaplanes coöperated with the fleet in the operations against the "Königsberg" on the E. coast of Africa.

Increased activity of enemy submarines led in Feb. 1915 to the building of a small airship known as the S.S. type (Submarine Searcher). Whilst this small airship proved successful within its restricted radius of action, an airship with a longer effective range was found to be necessary and the "Coastal" type was designed. Some 30 of these ships were eventually ordered. This development necessitated the establishment of various airship bases around the coast. In Nov. 1915, a scheme for the establishment of a large central school exclusively for the R.N.A.S., but similar to the Central Flying School, was proposed, and resulted in the establishment of training stations at Cranwell and Frieston early in 1916. In that year also a school for training both R.N.A.S. and R.F.C. personnel was opened in France. The policy of offensive patrols started by the R.N.A.S. units at Dunkirk during the latter part of 1915 was developed throughout 1916 and they worked in close coöperation with the R.F.C. on the western front.

At the end of Feb. 1916 a squadron of Sopwith 1½-strutter machines was formed with the intention of bombing factories in the Essen and Düsseldorf districts, the raids being carried out from England. Instead of this, however, the squadron was eventually used for long-distance bombing from French territory and was designated the 3rd Wing R.N.A.S.[1] A considerable number of raids were carried out by this wing, which was based near Belfort. During 1916, too, the activities of the R.N.A.S. in the Mediterranean and in E. Africa were increasingly prominent; and at home additional stations were formed round the coast, mainly for anti-submarine and anti-Zeppelin patrol. In the course of the year valuable coöperation was given to the army by squadrons of the R.N.A.S. operating on the French front, in Palestine, at Salonika, and elsewhere. The year 1917 marked the definite realization of the bombing policy already adopted by the R.N.A.S. Handley Pages and DH4 machines began to be delivered in the spring of 1917, and special bombing squadrons were organised at Dunkirk. Considerable development took place, too, in the employment by the R.N.A.S. of "lighter-than-air" craft in anti-submarines operations and in escorting convoys.

When the war started, the airships available for the R.N.A.S. were the former army airships, "Beta," "Gamma," "Delta" and "Eta," and the Naval Airships 2, 3 and 4, the total personnel employed in airship work being 23 officers and warrant officers and 171 ratings. During 1915, as already noted, new types of airship, known as "Submarine Searchers" and "Coastals" were added; and at the end of 1916 the strength of the naval airship service had risen to 192 officers and 1,540 ratings.

During 1917 standard designs for the different classes of airships were adopted. The "Submarine Searcher" had evolved into a type called the S.S. Zero, and an improved "Coastal" (designated C-Star) was adopted. New ships of the rigid type were also being built, two of which (R27 and R29) were completed in the spring of 1918. The next ships to be completed were the R31, constructed mainly of wood after the Schütte-Lanz design, and a sister ship, the R32, followed by R33 and R34. At the time of the Armistice there were five rigid and 98 non-rigid airships of different classes in commission. The personnel totalled 580 officers and 6,580 ratings.

III. Administrative System.—As already indicated, the British army and navy, at the opening of the World War, had separate administrative organizations for their air services. It was not till the creation of the Air Ministry in 1917–8 that the two were amalgamated. At the War Office, before that, the directorate of military aeronautics was divided into its own technical branches; and its organization developed under further technical subdivisions, as the duties to be dealt with increased in complexity and volume. Similarly, the organization of the Admiralty Air Department was subdivided in administrative sections.

It was inevitable that, even with the best will in the world, the two departments would enter into competition with one another for personnel and material; and as the war progressed this question became acute. Early in Feb. 1916, the Prime Minister appointed a "Joint War Air Committee," to coördinate, design and supply material for the naval and military Air Services. In addition to the chairman, Lord Derby, the committee included representatives of the War Office and the Admiralty, with Lord Montagu of Beaulieu as independent advisory member. This committee was authorized to refer any question disputed between the Admiralty and the War Office to the Government. After two months, however, this committee collapsed, following on Lord Montagu's resignation. Since the chairman was not himself a member of the Government he lacked the necessary authority to arbitrate between two great departments of State, each of which had its own organization, *esprit de corps* and aspirations; moreover, no clearly defined division of functions was adopted between the War Office and the Admiralty.

The next attempt at reorganization was the formation of the first Air Board in May 1916, with Lord Curzon as president, the other members being Lord Sydenham, Rear-Adml. Tudor, Rear-Adml. Vaughan Lee, Lt.-Gen. Sir David Henderson, Brig.-Gen. Brancker, and Maj. J. L. Baird, M.P. It was to be free to discuss policy and make recommendations to the War Office and Admiralty, but had no authority with regard to policy. It could, however, recommend types of machines for the army and navy Air Services. If either the War Office or the Admiralty declined to follow the Board's advice, the Board were empowered to refer the matter to the War Committee of the Cabinet. It was further charged with the organization and coördination of supply and material, and with the prevention of competition between the two fighting departments. It was provided that the Board should discuss air problems with representatives of the army and navy and such bodies as the Naval Board of Inventions and Research, the Inventions Branch of the Ministry of Munitions, the Advisory Committee for Aeronautics, National Physical Laboratory, etc. It was laid down also that the Board should be provided with a secretariat.

[1] The original 3rd Wing had been disbanded on the withdrawal of the Dardanelles expedition.

On the formation of Mr. Lloyd George's War Cabinet in Dec. 1916, Lord Curzon resigned the position of president and Lord Cowdray took his place in Jan. 1917. This second Air Board came into being under the New Ministries and Secretaries Act of 1916; and under this Act the president of the Air Board was specifically "deemed to be a Minister," and the Air Board a "Ministry." An Order in Council of Feb. 17 1917 laid down that the Board, in addition to the president, should consist of (*a*) the Parliamentary Secretary, (*b*) the appropriate member of the Board of Admiralty; (*c*) the appropriate member of the Army Council; (*d*) the two controllers of aeronautical supplies and of petrol engines in the Ministry of Munitions; and such additional members as might be appointed by the president.

For carrying out its duties the Air Board comprised a secretariat, a technical department, and a directorate of requisitions and statistics. Towards the end of 1917 the staff of the technical department was composed largely of officers drawn from the naval and military Air Services. Its duty was to consider and advise the Board as to the design of aeroplanes, seaplanes, engines and accessories, and, with this object, to carry out the necessary experiments and trials, and to keep in close touch with the scientific bodies and committees which were concerned with aeronautical research.

When the Admiralty and the War Office communicated to the Air Board the numbers of aeroplanes, seaplanes, and accessories required by the two Services for a given period, and when the Air Board had determined to what extent these requirements could be complied with and had come to a decision regarding design, requisitions were passed to the Controller of Aeronautical Supplies, whose department (a section of the Ministry of Munitions) was also housed in the Air Board Office. The Air Board also dealt with similar requisitions by Allied Governments (other than those in connexion with lighter-than-air craft and wireless telegraphy).

The director of requisitions and statistics kept analytical records of requirements, etc., and of the progress made in construction. A Central Air Intelligence Division was also established.

Aeronautical inventions were referred for consideration to an Inventions Committee, which was in touch with the Advisory Committee for Aeronautics, and the National Physical Laboratory. The department of the Controller of Aeronautical Supplies (Ministry of Munitions) placed contracts in accordance with the designs approved by the Air Board and carried out inspection during manufacture. The Controller of Aeronautical Supplies also had the Royal Aircraft Factory under his administration.

In addition to the departments of the Air Board and of the Controller of Aeronautical Supplies, there were also housed in the Air Board Office the H.Q. administration of the R.N.A.S. under the Fifth Sea Lord and Director of Air Services, and that of the R.F.C. under the Director-General of Military Aeronautics.

With sundry expansions in internal organization this Air Board continued to function until the new Air Ministry was created at the end of 1917, absorbing the existing Air Board organization as well as the military aeronautics directorate and the Admiralty Air Department (although a "division" with a similar designation was still retained at the Admiralty).

The Air Ministry came into being under the Air Force Constitution Act (1917), which provided definitely for the amalgamation of the two flying services under the title of the Royal Air Force. In accordance with this Act the Air Ministry was constituted as a department of State, the final authority being vested in an Air Council which was formed in Jan. 1918 as follows:—

The Secretary of State (president), chief of the air staff, deputy chief of the air staff, master-general of personnel, controller-general of equipment, director-general of aircraft production, administrator of works and buildings, parliamentary under-secretary.

IV. The Royal Air Force.—The Royal Air Force itself did not come into being until April 1 1918. At that time the R.F.C. at home consisted mainly of (*a*) the Training Division, (*b*) the 6th Brigade (Home Defence), (*c*) the Balloon Wing, and (*d*) miscellaneous establishments. The R.N.A.S. units were organized into a number of groups directly under the Admiralty.

On the formation of the R.A.F. the United Kingdom was divided into five areas, comprising all units of the new service (with the exception of a few directly under the Air Ministry). Each area was further subdivided into groups. The Training Division and its brigades were done away with, the former's functions being assumed by the training directorate of the Air Ministry. The technical administration of airship stations remained under the control of the superintendent of airships at the Admiralty, naval operation groups were under the naval commander-in-chief concerned for operations, but their maintenance and administration was the concern of the appropriate area headquarters. Units of the R.A.F. serving with the Grand Fleet were entirely controlled by the commander-in-chief.

At the same time it was decided to form an Independent Air Force. In Oct. 1917 it had already been decided to return to the policy that had been visualized when, in 1916, the dispatch of the 3rd Wing R.N.A.S. to Belfort was being contemplated. Squadrons No. 55, 216 and 100, were then sent to the Nancy area, and they carried out bombing operations against German towns during the closing months of the year and the spring of 1918. By April 1918 the 8th Brigade, as the force was designated, had been reënforced by No. 99 Squadron; and when now it was reëstablished as the Independent Air Force six more squadrons (104, 97, 215, 115, 110 and 45) were added.

In planning the post-war organization of the R.A.F., it was assumed that in the immediate future nothing in the nature of a general mobilization need be contemplated, that efforts should be concentrated on providing for existing needs, and on founding a highly trained and efficient force, inherently capable of expansion should the necessity arise. The purpose was, accordingly, to limit the number of service squadrons to what was considered essential to meet existing responsibilities, to devote the remaining resources to perfecting the training of officers and men, and to construct a sound framework on which to build the R.A.F. of the future. In forming the framework it was felt that the main portion of the R.A.F. would consist of an independent force, together with the personnel required to carry out aeronautical research. In addition, there would be a small part of it specially trained for work with the navy, and a small part specially trained for work with the army. It seemed possible that the main portion, the Independent Air Force, would grow larger and larger, and become the predominating factor.

The training for officers and men is briefly as follows:—The channels of entry for permanently commissioned officers are through the Cadet College at Cranwell, from the universities, and from the ranks. The Cadet College is the main channel. The course lasts two years, during which the cadets are thoroughly grounded in theory and practice and learn to fly the approved training machine. On leaving the College, the cadets are commissioned and posted to a squadron. Apart from courses that every officer will normally pass through, such as gunnery and air pilotage, officers will be required, after five years' service, to select the particular technical subject they will make their special study during their subsequent career, *e.g.* navigation, wireless, engines.

The career of an officer commissioned from the universities or from the ranks will be identical with that of those from the Cadet College, except that they will be taught to fly at training wings before joining the squadron. Short-service and seconded officers will be taught to fly at training wings, and will attend a course of aerial gunnery and probably one of air pilotage.

With regard to the other ranks—the most difficult problem—it was decided to enlist the bulk of those belonging to long apprenticeship trades as boys, who will undergo a course of three years' training before being passed into the ranks. The boys, on successfully passing their final examination, will be graded as leading aircraftsmen, and a certain number will be specially selected for a further course of training, at the end of which they will either be granted commissions or promoted to N.C.O.'s. Those granted commissions will join the Cadet College. The mechanics, of whom more than half will belong to short apprenticeship trades, are enlisted as men and receive 12 months' training before being posted to units. Non-technical men are given a short course of recruit training at the R.A.F. depot at Uxbridge.

The R.A.F. estimates for 1920–1 provided for an establishment of 29,730 officers, warrant officers, non-commissioned officers, aircraftsmen and boys (exclusive of those serving in India).

V. The Future of Air-Fighting.—It is now universally recognized that in future wars the operations of naval and land forces will be largely influenced by the degree of assistance that can be rendered by aircraft. It is equally clearly understood that such assistance can only be rendered to the full extent of the resources available if air supremacy has been definitely established and can be successfully maintained. It is realized that, as is the case with sea command, air supremacy is an issue that can only be settled by combat (assuming a certain degree of equality and of readiness to fight in the opposing air forces). It is therefore by the air fighting and consequently by the air fighter that subsequent operations, whether on sea or on land or in the air, will be influenced.

Whether the last word in air fighting would always rest with the small, swift, easily manœuvred machine was in 1921 still an open question. It is possible that we shall see, in the future, armament replacing speed as the determining factor in aerial

tactics, and that aerial battleships will be evolved capable not only of fighting but of carrying the war into the enemy's country and crippling his power of resistance in the early stages of the struggle. It is in recognition of this principle that the French Military Air Service has been divided into formations the functions of which are purely ancillary to the army, and into formations whose functions it is first to establish air supremacy and secondly, when its attainment makes it possible, to develop the essentially offensive form of aerial war, the long-distance bombing raid. Accordingly, in addition to coöperating formations, the French maintain what is analogous to the British Independent Air Force, a force composed entirely of fighters and bombers.

There is no doubt that ultimate air power must depend largely upon the place of aviation in the economic life of the community, but this does not mean that air power is focussed entirely in a flourishing civil industry. The suddenness and effectiveness that lies in aerial action must not lead to a striking force being held in constant readiness to act whenever war appears imminent. The manner of employment of this force, and the efficiency it displays, may have a vital bearing upon the subsequent course of the war, and no country would risk doing altogether without some form of standing military air force.

There is also every indication that civil and military aircraft will tend to develop along divergent lines, and that the civil machine will never be a factor in air supremacy excepting as an auxiliary. The most important factor in the civil machine is productive economy, whereas the designer of service craft strives for destructive performance; and individual aircraft can hardly be equally efficient for both purposes. (A. W. H. E. W.)

VI. GERMAN AIR FORCES.—Before the World War, the German military air service, in splitting off from its parent body, the Pioneers, had been made administratively part of the Communication Troops. From Oct. 1912 the Flying Troops had formed a separate entity within the Communication service. Nevertheless, when it took the field in Aug. 1914, and for some months thereafter, they were still nominally under the inspector-general of Communication Troops, an arrangement which worked badly in practice besides tending to prevent the growth of *esprit de corps* in the flying service. It was not till Aug. 25 1915 that it was freed from this control.

But already on March 11 1915 all German formations serving at the front had been placed under a "*Chef des Feldflugwesens*," and a month later this officer (Col. Thomsen) was made the official superior of all other army services as well, his functions including control of all motor transport included in the air establishment.

About the same time a staff officer for aviation was appointed to the H.Q. of each army, but it was not until Nov. 1916 that this officer was renamed "*Kommandeur*" and placed in executive command of the air forces within his province.

Somewhat earlier than this, on Oct. 8 1916, Gen. von Hoeppner had been appointed "*Kommandierender General*" of the military air forces, with Thomsen as his chief of the staff. As in the German army system a "*Kommandierender*" (*i.e.* Commander of an Army Corps and its Region) enjoyed wide powers, both under the laws and under the regulations, and as the office of chief-of-staff likewise carried with it known and definite powers, the status of the air force was for the first time thereby assured. Moreover, the commanding general, not being under any army or group of armies H.Q., had direct access to G.H.Q. From this point, the organic development of the air force went on straightforwardly. But it is interesting to note that even in the German system, with all its sense of order and organization, conservatism sufficed to delay the consummation till nearly two and a half years after the outbreak of war.[1]

In spite of army proposals however, no single command was ever created in German military and naval air forces, which remained wholly separate to the end. One retarding influence was the particularism of the various German states. The Württemberg Government, for instance, gave formal orders to its own aviation depot unit not to supply flying officers to any but Württemberg units.

The working organization in the field as finally developed was as follows:—The commanding general had his own H.Q., and reported direct to the chief of the general staff of the army. His immediate air service subordinates were the "*Kofls* (*Kommandeur der Luftstreitkräften*)," one to each army, with as above mentioned, occasional groupings of the forces of several armies under one "*Kofl*." Under his orders, flights of aircraft were commanded by group commanders (instituted 1917) who gave instructions to the flight commanders and through whom their *liaisons* with the military command, and especially the artillery, passed.

At each corps H.Q. a staff officer looked after both operations and *liaison*.

In the earlier years of aviation, the confidence of the German authorities and public in the lighter-than-air ship retarded the growth of aviation. But in 1912 the dangers of further neglecting the aeroplane were realized, and an active propaganda resulted in a national subscription for the manufacture of aeroplanes and the training of pilots. In the autumn of the same year an army flying school was provisionally established and this became permanent in the spring of 1913. At the moment of mobilization 254 pilots and 271 observers were available.

The following summary of the development of German aviation units during the war, while necessarily brief, will serve to show how the needs revealed by war experience were successively met by changes of organization.

In the beginning, German aviation units like others were for general service, the same machines (two-seater fighters) serving all purposes, reconnaissance, spotting, bombing and fighting.

In the middle of 1915 came the first specialization of functions—the separating out of air-fighting elements. These units (two-seater fighters) were originally known as "battle squadrons" and had the rôle of barring the German front line against Allied aircraft as well as such bombing as was then done. But the necessities of aerial combat very soon produced a further subdivision on this side, "Fokker" flights (of single-seaters, equivalent to British "scouts") undertaking the offensive air battle and the residue the protection barrage and the bombing. Presently they too subdivided into protective flights and bombing flights (the latter being grouped later in squadrons).

When the fighting elements separated off from the reconnaissance elements, the latter (organized in flights only and allotted as required to groups) were limited to their proper functions, and a further specialization presently came about by which artillery flights were separated from reconnaissance flights. In these artillery flights the personnel was largely, if not entirely, drawn from the artillery, but their special character did not prevent them from being used occasionally for photographic work. Many, though not all, artillery flights were equipped with wireless telegraphy apparatus.

The high-fighting "*Fokker abteilung*," always increasing in numbers as it became more and more evident that the British policy of offensive protection was the true one, developed into the "pursuit flight" (*Jagdstaffel*). Occasionally, a number of these pursuit flights were grouped into a semi-permanent squadron under a leader of note, *e.g.* Richthofen; a squadron of this kind was colloquially and very aptly called a "circus," both on account of the acrobatic powers of its members and the fact that it moved up and down the front as its services were required to obtain local control of the air.[2] The old "*Kampfgeschwader*," charged with protective barrage and with bombing, was also subdivided into two parts—the so-called protective flight, whose duty was local escort for friendly, and local barrage against enemy reconnaissance machines, and the pure bomber, for whom more and more powerful machines were evolved and whose radius of action was constantly increased.[3]

Lastly, the protective flight, whose defensive function was discredited, became a battle flight (*Schlachtstaffel*). The practice of low-flying for direct intervention in a ground battle had been growing steadily since the battle of the Somme, and in the German and Allied offensives of 1918 it attained a maximum. In contrast to the British custom of training and trusting flights of the reconnaissance type (called contact patrols) to carry out this dangerous duty, the Germans treated it as an essentially combatant function, and used for it a branch of the aviation service which had always belonged to the fighting as distinct from the reconnaissance side. In the last phase some of the battle flights had armoured machines.

On the combatant side therefore, German aviation was finally classified into three branches: pursuit flights (high-fighting for command of the air, with 18 machines per flight); bombing squadrons (long-distance bombing, with about 24 machines per squadron); battle flights (low-fighting in connexion with ground operations, *i.e.* bombing and machine-gunning of troops and transport, with six to twelve machines per flight, average about eight). One other type of fighting unit was created for air defence at home. It was known as the "*Kampfeinsitzerstaffel*" (single-seater battle flight), and restricted to local defence of munition areas, etc.

From statistics given in Neumann's *Die deutschen Luftstreitkräfte*, it appears that, apart from reserve machines, the Germans employed for various purposes during the war 220 machines in 1914, 480 in 1915, about 1,100 in 1916, about 2,300 in 1917, and about 3,800

[1] Shortly after the creation of the "Commanding General," some grouping of air forces within the group of armies was effected by making the "Air Force Commanders" of one of its armies responsible for coördination of effort, and to a certain extent for distributing forces as well.

[2] After Richthofen's death his squadron was officially designated by his name and the number 1 as a permanent organization. Two other squadrons were formed in the summer of 1918.

[3] The original bombing squadron was a group set aside in 1915 for the ultimate purpose of bombing England from Calais, when that port should have been occupied by the Germans. The rapidity of air evolution in the war is well shown by the fact that within a year of that date, London was bombed by an aeroplane based on Ghent.

in 1918. Interesting and significant figures are given by the same author as to numbers and losses in personnel, and expenditure of *matériel*. In actual flying personnel at the front, the highest total present at one time (in 1918) was about 5,500, with a like number under training at home. The total deaths of flying personnel or candidates in the war numbered 6,840, of whom about two-thirds died at the front. The number of wounded and injured (7,350) is little more than that of the dead. Approximately 2,128 planes were lost under known circumstances (about 1,900 of these on the western front). In addition about 1,000 missing were presumed as lost. In all, 47,637 machines and 40,449 motors were taken on charge from contract. The monthly expenditure of fuel at the end of the war was 7,000,000 kgm., and the total for the whole war about 232,000,000 kgm. Rather over a million bombs were dropped, of which 860,000 were of the 12-kgm. type and 710 of the monster 1,000-kgm. type.

The organization of German naval aviation before the war was considerably in arrears as compared with that of army flying. The predominance of the airship was the main cause of this, but other causes contributed, especially, it is said, the lack of interest in seaplane design on the part of manufacturers, whose establishments (except that of Friedrichshafen) were far from water. The first seaplane competition, organized by a few enthusiasts, was to have been held on Aug. 1 1914. Only some 20 naval officers had been trained as pilots in the single existing seaplane station.

These conditions continued to hamper progress for some time after the outbreak of war, as the army impounded all the motor manufacturing resources for its own needs. Nevertheless, seaplanes were established on the Flanders coast by Dec. 1914, and thereafter the organization of the seaplane service expanded till there were finally 32 stations in the different theatres of war and on the German coast. For naval work, the organic unit was the station; the equipment, of course, varying according to the work expected of each station.

At the same time, a number of aeroplane flights organized as such, were created by the navy for land service, of which nine or ten served in the eastern and south-eastern theatres. The other fifteen, in Flanders, belonged to the Marine Corps, a mixed organization responsible for the land defence of the Yser front, the coast defence of the Belgian coast and the submarine operations based on that coast. The commander of Flying Troops of that corps had under him a correspondingly mixed air force.

Naval aviation generally was under the control of a naval aviation chief, who was independent of the army air authorities.

*Airship Organisation.*—In spite of the popular enthusiasm evoked by the work of Count Zeppelin and other airship constructors before the war, the naval and military authorities were not, before the war, very ready to commit themselves to a strong and permanent air organization. The army airship organization dated only from 1906–7 and the naval from 1910–1. The army acquired Z1 in 1906 and Z2 in 1909, and after the wreck of the latter, a pause occurred in which commitments were avoided pending further competitive experiments between the Zeppelin, Parseval and Gross types. In 1912, however, the decision went in favour of the Zeppelin and the Schütte-Lanz, and airship battalions were formed to fly and to maintain airships.

At the outbreak of war the army possessed seven ships (six Zeppelin and one S-L) of the rigid type, and two others, and took over three more from private ownership. Organization, nominally by battalions, was in reality dependent on the number and station of ships. This rapidly increased. But from the first there was a strong current of opinion adverse to the airship in land warfare, and the authorities concerned with personnel looked with disfavour on the huge landing parties which the ships required at each station. In spite, therefore, of the occasional achievements of individual ships,[1] it was decided early in 1917 to discontinue the army airship service. The still useful ships were handed over with part of the air personnel to the navy, and the remainder of the personnel was allocated to the army kite balloon service.

Excluding Parseval and small airships—the manufacture of which was discontinued at the outbreak of war—37 Zeppelin and 10 S-L ships were commissioned by the army from first to last, of which 17 were lost in action, 9 lost from other causes, 17 scrapped, and 4 handed over to the navy on discontinuance.

The navy, on the other hand, beginning later than the army, went on developing the airship service to the end of the war. In Aug. 1914 it possessed only one ship, obtained from the Zeppelin company to replace Government ships lost in 1913.

Inclusive of the effective ships taken over from the army in 1917 74 ships were commissioned for naval service, of which 23 were lost in action, 30 from other causes (4 by lightning), and 11 were scrapped.

*Kite Balloons.*—The development of dirigible airships and of aeroplanes, in Germany as elsewhere, thrust the captive balloon into the background, and although 8 field and 15 fortress balloons were mobilized in 1914, the question of their abolition was actually being considered when the unexpected coming of trench warfare opened up a new field for them. Early in 1915 the introduction of power winches (at first improvised in the field) and of the parachute added greatly to their efficiency, and by the end of that year more than 40 sections, each of 2 balloons, were in the field. But the war experience of 1916, and notably the sight of Allied sausage balloons, hanging in the air "as thick as grapes," compelled the army authorities to develop their kite balloon service at a faster rate. The organization, hitherto in single unconnected sections, was expanded to provide over 50 staffs, each of which controlled 2 to 3 sections of balloons. In the end, 184 such sections existed in the field, as well as a certain number lent to Turkey or employed in instructional duties. In the latter part of the war the admittedly inferior balloon of German design was replaced by one of the Caquot type, a captured specimen being copied almost exactly.

In all, 1,870 kite balloons of all types were delivered from contract and about 350 power winches. In course of the war about 600 balloons were lost in action (75% to 80% by aeroplane attack), 100 by weather and other causes, and 500 condemned as unserviceable.

The *Meteorological Service* in the German army formed part of the air forces, although its observations and reports served the artillery, chemical warfare and other branches as well. At the beginning of the war an embryonic organization already existed, with a central section at Berlin, 14 sections at airship stations and aerodromes and 2 sections organized on a mobile basis. These last at once expanded to 8 (one per army) and by the close of the war these 23 units had grown to a total of 316.

The general lines of the organization were as follows:—(1) The Berlin H.Q.; (2) Western Front H.Q. at Brussels; (3) Eastern Front H.Q. at Warsaw; (4) South-eastern Front H.Q. at Temesvar (later Sofia), and (5) Turkish H.Q. at Constantinople. Under each of these (except the last) there were in strength varying according to conditions, *Hauptwetter Warten*, which were concerned with focussing information from Berlin, from the naval weather service, and from the front, and also with local meteorological services for troops behind the line in occupied areas (*e.g.* flying schools); and *Armee Wetter Warten* which had the chief tactical and technical responsibility at the front, and controlled a network of minor units, some attached to particular services but most distributed on an area basis.

*Air Defence.*—In Germany and at the front the commanding general of air forces was responsible for air defence. A few mobile guns only were available for anti-aircraft work in 1914, but the 75-mm. guns captured in the advance to the Marne and especially the high velocity Russian field guns taken on the eastern front, provided a considerable A.A. armament, pending the design and supply of special ordnance. By the end of the war the original 20 guns had grown to a total of over 2,000. The evolution of technical adjuncts of air defence, searchlights and direction-finding detectors (*see* AIR DEFENCE), proceeded as on the Allied side.

As regards organization, after various alternative methods had been tried, the Germans separated off all "*Flak*" (*Flugabwehr Kanone*) troops from the rest of the artillery and centralized the control in each army area in the hands of a special officer, to whom all subordinate *Flak* commanders were alone responsible though they were authorized to advise corps commanders on the technical aspects of air defence in the corps area. In 1916 the *Flak* service passed with the rest under the control of the new commanding general of air forces; thenceforward all the means of air defence were coördinated under the same authority in each area, both in the field where "Commanders of air forces" (see p. 87) exercised local control, and in Germany, where a deputy of the commanding general was responsible for defence of munition areas. This organization ensured an intimate connexion between guns, aeroplanes, observation posts and lights, based on a common doctrine taught in the *Flak* depot at Freiburg and in *Flak* schools at the front.

VII. UNITED STATES.—In the United States, as elsewhere, the organization of air forces before the World War was in its infancy, and although between 1914 and the entry of the United States into the war a certain amount of air research and training had been carried on, and some practical war experience gained in Mexico, yet their position as neutrals prevented the American authorities from obtaining technical data concerning the progress in aviation that was evidently being made by the belligerents.

In April 1917, therefore, when the Allies invited America to train and equip a force of 5,000 aviators for service in Europe, there was little likelihood of the demand being met. At that date the American forces possessed 55 machines of which a scientific commission had just declared 51 to be obsolete, and about 75 trained officer pilots.

The first necessities, therefore, were instructors and training machines. Of the latter, or rather of a type of the latter considered good enough for primary instruction, delivery in quantity began before the winter of 1917, and by the Armistice there were about 9,500 planes and 17,500 engines suitable for training.

The need of instructors was met partly by borrowing British and French officers, and partly by retaining the best pupils in the early classes to become instructors to those formed later. In the sequel, 8,600 pilots were graduated from the elementary courses and 4,000 from the advanced courses before operations ceased, and some

[1] In many respects the most remarkable achievement of airships in the war was the voyage of L59 in the autumn of 1917. This was a naval ship, but the service in question was overland. Starting from Yamboli in Bulgaria the attempt was made to reach von Lettow-Vorbeck in E. Africa with medical and other small and valuable stores. This ship was recalled by wireless after passing Khartum, but returned safely, after a 7,000-km. voyage lasting 96 hours. The record for endurance, however, was held by LZ120 (101½ hours).

6,500 more were at that date in training. After graduating from the advanced course, pilots and observers joined the expeditionary forces where they underwent a final training before going into action. The total of qualified flying officers in March 1918 was 2,248 in the United States and 650 overseas; these numbers had grown in July 1918 to 4,974 in the United States and 2,692 overseas, and in Nov. 1918 to 7,118 in the United States and 4,307 overseas (of whom, however, only 1,238 were as yet at the front). Inclusive of ground personnel and students, the total personnel of the U.S. air forces was nearly 200,000 at the date of the Armistice.

In the production of service machines for these men to fly, grave difficulties arose, none the less grave because in the excitement of the time unreasonable expectations had been formed and encouraged.

After study of the problem, not only from the standpoint of qualitative efficiency in the machine but also from that of man production, the British DH4 (observation and day-bombing) and the Handley Page and Caproni night-bombers were selected as standard types for American production, being redesigned to take American motors.[1] For pursuit flights, only non-American machines were employed. At the end of the war, out of the 7,889 service planes on charge, about half were American-built, and of the total of 22,000 engines nearly three-quarters.

With kite balloons, these supply troubles seem hardly to have existed. From zero (or rather from an establishment of 20 borrowed balloons) in Jan. a total of 662 had been reached by Nov., of which 43 had been destroyed, 35 handed over to the British and French, leaving 574 in service.

The organization of the American air forces in the field was by squadrons, classified as pursuit, observation, day-bombing and night-bombing. The premier American squadron was one of American volunteers, the "*Escadrille Lafayette*," which had been serving in the French army and was transferred to the U.S. army in the winter of 1917–8. In the spring of 1918 squadrons formed and came into the field in twos and threes, but in the late summer DH4 machines became available in large numbers, and observation and day-bombing squadrons began to increase more rapidly. From a July total of 15 squadrons, the figure of 30 was reached in Sept. and 45 in the first week of Nov. (exclusive of balloon companies in each case). The machines, however, were still preponderantly of foreign make. Twenty-six squadrons and 14 balloon companies took part in the St. Mihiel battle, and 45 squadrons with 740 machines, and 23 balloon companies in the final Meuse-Argonne battles.

(C. F. A.)

**FOCH, FERDINAND** (1851– ), French marshal, was born at Tarbes Oct. 2 1851, his father being a civil official and his mother's father an officer of Napoleon's army. Educated at Tarbes, Rodez, and finally at the Jesuit colleges of St. Michel (Loire) and St. Clément (Metz), he was preparing for the entrance examination for the École Polytechnique when the war of 1870 broke out. He enlisted in the army, but saw no active service, and returned to Metz, then in German occupation, to complete his studies, entering the École Polytechnique in Nov. 1871. On being commissioned in 1873 he was posted to the artillery, in which arm the whole of his regimental service was spent. As a captain, he became a student of the Staff College (École de Guerre) in 1885 and left, with fourth place, in 1887. From this time till 1901, save for a period in which as major he commanded a group of horse artillery batteries, his work lay in the general staff of the army, the staff of formations and the École de Guerre. It was in the École de Guerre that he developed his doctrines and his influence on the education of the army. From 1895 he was assistant-professor, and from 1898, as lieutenant-colonel, professor of military history and strategy in that institution, first under Gen. Langlois, and then under Gen. Bonnal, the two leaders of military thought whose work, with his own to complete it, established the new French doctrines of war, based on re study and application to modern conditions of Napoleon's practice. This is the key idea of Foch's classical treatises, *Principes de Guerre* and *La Direction de la Guerre*.

Foch's career as a professor at the École de Guerre lasted hardly more than five years. The army was at that time in the midst of acute political troubles. The Minister of War, Gen. André, was engaged in a drastic, and not overscrupulous attempt to make the army safe for democracy; the Dreyfus affair was running the last stages of its fierce course, and, in his responsible post at the École de Guerre, Foch was an obvious target of attack, as an openly devout and practising Catholic, educated under Jesuit influence. He was returned to regimental duty, and his promotion to colonel only took place in 1903.

In 1905 Clemenceau, then Prime Minister, determined to make use of his military ability to the full, irrespective of political considerations, and, after a short time spent as deputy chief of the general staff, he was appointed commandant of the École de Guerre. Already in 1907 he had been made general of brigade. In 1911 he was promoted general of division and in 1912 corps commander. In 1913 he was appointed to command the most exposed of all the frontier corps, the XX. at Nancy, and he had held this appointment exactly a year when he led the XX. Corps into battle. Foch was then the only intellectual master of the Napoleonic school still serving. And the doctrines of the brilliant series of war school commandants, Maillard, Langlois, Bonnal, Foch, had been challenged, not only by the German school (see 25.994), but also since about 1911 by a new school of thought within the French army itself, which, under the inspiration of Gen. Loiseau de Grandmaison (d. 1915), criticised them as lacking in vigour and offensive spirit, and conducing to needless dispersion of force. The younger men carried the day, and the French army took the field in 1914 governed by a new code of practice. But history decided at once and emphatically against the new idea in the first battles of August, and it remained to be seen whether the Napoleonic doctrine would hold its own, give way to doctrines evolved in the war itself, or, incorporating the new moral and technical elements and adapting itself to the war of national masses, reappear in a new outward form within which the spirit of Napoleon remained unaltered. To these questions, it must be admitted, the war has given an ambiguous answer which will long provide material for expert controversy.

It was, in reality, as a leader in the field, far more than as thinker, that Foch personally influenced the course of the war on the western front. His conduct of operations in the first battles before Nancy, as a corps commander, presents no special characteristics, but in a few weeks he was placed at the head of the newly formed IX. Army, to fill the gap in the line caused by the divergent directions of retreat of the IV. and V. This army he commanded in the battle of the Marne, being opposed to the German III. Army and part of the II. in the region of Fère Champenoise and the Marais de St. Gond. After several crises he finally repulsed the attack, and initiated a counterstroke round which a legend promptly grew up and on which was founded a popular reputation that, no doubt, gave Foch the one element lacking in his equipment for the highest commands—prestige. Almost immediately after the battle, when the mutual attempts of Allies and Germans to outflank one another's northern wing produced the so-called "race to the sea," Foch was designated assistant to the commander-in-chief and went north to coördinate the movements of the various French armies and eventually those of the British and Belgian armies concentrating towards Flanders. Over the French army commanders he possessed the powers of a commander-in-chief, but over the British and Belgian forces, like Joffre, he had no authority. This delicate relation, in the midst of one of the greatest crises of the war—one which for Britain and Belgium was of graver import than even that of the Marne,—inevitably led at times to friction between the coequal commands, and after the war a rather unworthy controversy was waged in the press as to some incidents of this period. But in sum, the reputation which Foch already enjoyed amongst European soldiers before the war, and the fact that he had long been in intimate relations with Gen. Sir Henry Wilson, deputy-chief of Sir John French's staff, enabled him to carry out successfully a mission with which no other general could have been entrusted.

After the battle of Ypres and the stabilization of the fronts, Gen. Foch commanded the French "Group of Armies of the North" during 1915 and 1916. In this period, under Joffre, he was responsible for the offensives in Artois during the spring and autumn of 1915, in which again he stood in close relation to the British on his left, though now the sectors of each were

[1] The British "Bristol Fighter," originally selected as one of the types, proved unsuitable for adaptation to American engines and was not adopted. It should be added that American machines were designed to suit these motors, but none had passed into quantity production at the Armistice.

exactly defined and there was neither a crisis nor an interminglingof forces such as those of the Ypres period. Moreover, the general headquarters of the two commanders-in-chief, Joffre and French, were now fixed, and the two armies made their liaison between St. Omer and Chantilly rather than through the local headquarters of Foch, who was no longer assistant commander-in-chief, but a subordinate.

In 1916 Foch's group of armies supplied the French element in the battle of the Somme. Towards the close of that battle, his reputation underwent a temporary eclipse, motived no doubt largely by the disappointment felt both in England and in France as to the results; but also and perhaps more by somewhat obscure domestic intrigues within the French staff. At that time the movement for Joffre's supersession had come to a head, and, it is said, his adherents within the headquarters sought to maintain him in power by suggesting that Foch, the most likely candidate for the place, was broken down in health. Though this did not prevent the removal of Joffre, it excluded Foch from the succession. Gen. Nivelle was appointed commander-in-chief, and a certain control by him over the British forces was agreed to by Mr. Lloyd George's Government, then newly in office. Foch was relieved of his command and sent first to the Swiss frontier to report on the possibilities of attack and defence in that quarter and then to Italy to negotiate with the Comando Supremo as to aid from France in case of a disaster to Cadorna's forces. But on May 15 1917, after the tragic failure of Nivelle's offensive and the supersession of that general by Pétain, M. Painlevé called Foch to Paris as chief of the general staff of the French army. But in this capacity his influence only became really effective after the accession to power of the Clemenceau Ministry in November. From that point to the events of March 1918, the evolution of Foch's authority was rapid. He was first, as adviser to Clemenceau and as a soldier whose counsels carried more weight than those of any other, a powerful indirect influence in the inter-Allied discussions as to the plan of campaign for 1918. Then as French member of the "Executive Committee," a sort of board of inter-Allied command founded in Jan. 1918, he took his place almost as *de jure* president of that body. Lastly, the storm of the German offensive broke on the British V. Army on March 21, and although Haig and Pétain managed by cordial coöperation to reconstruct the broken line and check the German advance, the situation remained so critical that the last step was taken. On March 27 Foch by general consent was nominated to coördinate the operations of the British and French in France. On April 14 the title and authority of commander-in-chief was granted to him by the two Governments concerned, and on April 15, April 17 and May 1 respectively by the Belgian, American and Italian Governments.

On Aug. 6 1918 Foch was made a marshal of France. In the interval the Germans had renewed their offensives four times, and more than once there had been a crisis as grave as that of March which Haig and Pétain had had to face, notably on May 27. But these crises had been surmounted, and towards the end of June, with his resources greatly augmented through the emergency measures taken by the American Government, the British sea transport authorities and Gen. Pershing in France, he could begin preparations for his counter-offensive. The story of the battles in Champagne in which the last German offensive and the first Entente counter-offensive coincided (July 15–18), of the battles on the Somme area about Amiens (Aug. 8) and Bapaume–Peronne (Aug. 21), and of the simultaneous offensives of the Americans on the Meuse–Argonne front, the British on the Cambrai–St. Quentin front, and the Belgian, British and French under King Albert in Flanders (Sept. 26–28) is told elsewhere (*see* also the article TACTICS). From Sept. 26 to the Armistice the whole front from the sea to Verdun was one continuous battlefield, controlled by one commander-in-chief. An extension of this battlefield into Lorraine, where the final blow was to be delivered on Nov. 14, was only prevented by the capitulation of the enemy.

After the war Marshal Foch received the highest honours from his own country and from the Allies. In one of his frequent visits to London he was created a field-marshal in the British Army, and he was also awarded the O.M. He became a member of the *Académie Française* in 1919. He had a great reception in the United States on his visit in 1921.

Various biographical sketches of Marshal Foch have appeared, for the names of which the reader is referred to any good subject index. The history of the single-command idea will be found in detail in M. Mermeix's *Les Crises de Commandement* and *Le Commandement unique* (part I.) and that of the internal politics of the French headquarters in the same, and in J. de Pierrefen's *G. Q. G., Secteur I.* (2 vols.), Paris 1920. The story of his final campaign, from the point of view of Foch's headquarters, is given in Louis Madelin's *La Bataille de France* and R. Recouly's *La Bataille de Foch*.

**FOGAZZARO, ANTONIO** (1842–1911), Italian novelist and poet (*see* 10.590), published in 1910 his last novel, *Leila*, a sequel to *Il Santo*. He died at Vicenza March 7 1911. *Ultime*, a volume of his latest writings, appeared in 1913.

A collection of records and memorials of the poet was published in two volumes in 1913–4. See also Eugenio Donadoni, *Fogazzaro as Man and Writer* (1913); L. Gennari, *Fogazzaro* (1918); and A. F. Crispoliti, *Antonio Fogazzaro; Discorso commemorativo* (*1911*).

**FOOD SUPPLY.**—During the World War of 1914–8 practically all the belligerent and neutral countries of Europe experienced a shortage in the supply of food and other necessaries. The shortage was traceable to three distinct causes: first, the diversion of productive power to destruction or to making the means of destruction; second, the increased rate of consumption of those who were fighting or were undertaking harder physical labour than usual in the production of munitions; third, the deliberate blockades which with varying success the belligerents directed against one another and against neutrals. The blockades had as one feature a destruction of shipping which is perhaps sufficiently important to be reckoned as a fourth cause of shortage, additional to the other three. These causes of reduced supply or increased demand applied more or less to all useful artscles; they naturally produced their most sensible effects in the case of necessary articles and above all in that of food. There, the failure of the ordinary channels of supply to meet the demand sooner or later became in every European country so serious as to call for direct intervention by the Government and to make "food control" one of the features of the war. Every country had its succession of food controllers.

The degree of the food shortage and the methods available or adopted for dealing with it naturally varied from one country to another. In all of them it may be said that the food controller had three main problems to consider, namely, the maintenance of supplies, the regulation of prices, and the control of consumption by distribution and rationing. The three problems are naturally connected. A solution of the first of them so complete as to keep supplies up to or above the pre-war standard would prevent the other two from arising at all or at least in any serious form; this happened with bread-stuffs in the United Kingdom. On the other hand an attempt to fix prices without controlling supplies would lead either to a disappearance of supplies or to their distribution in an unjust and wasteful manner. While the problems are thus connected, the third of them— distribution and rationing—can to some extent be described separately and is so described under the heading of RATIONING. The present article will deal mainly with the action taken in respect to supplies and prices and will touch on distribution and rationing only to indicate points of contact. No attempt can be made here to describe, even in outline, food control in all countries. All that can be attempted is to give some account of what was necessary and what was accomplished in the United Kingdom, and to mention the salient points of similarity or difference in the experience of other countries.

For the first two years of the war questions of food control attained little prominence in the United Kingdom. The cutting off of the Central European sources of sugar supply led to the anticipation of a considerable shortage of that particular food, and a Royal Commission was established in Aug. 1914, which undertook on Government account the purchase and importation of all supplies from that time onwards. A special organization

for securing army meat from abroad was also found necessary from the beginning; this involved control of refrigerated tonnage under the Board of Trade. A system for obtaining weekly reports on retail prices (mainly through the staff of the Labour Exchanges) was put into action at the outbreak of the war; these reports yielded material for subsequent estimates of the increase of the cost of living. The use of cereals and sugar for brewing was limited by an Output of Beer Restriction Act, coming into force on April 1 1916. Apart from this, food supplies were allowed for two years and more to take their course.

By the autumn of 1916, prices, which had risen more or less steadily from the beginning of the war, reached a level which began to evoke acute discontent, and the prospects of an intensified submarine campaign caused anxieties for the future. Two important steps were taken. The first was the establishment in Oct. 1916 of a Royal Commission on wheat supplies, parallel to that on the sugar supplies. This Commission almost immediately took on an international character through the signing in Nov. 1916 of the "Wheat Executive Agreement" between Great Britain, France and Italy, under which the purchase, importation, distribution and shipping not only of wheat but of all cereals was arranged on a common basis for the three Allies, the administrative work being undertaken in London. The Wheat Executive gradually extended its activities to other allies and even to neutrals. The Wheat Commission and the Sugar Commission retained their existence as separate bodies even after the appointment of the food controller, but the latter in practice decided questions of policy and became responsible for supplies of cereals and sugar as of all other foods.

The second step was the making of an Order in Council under the Defence of the Realm Act (Nov. 16) which practically empowered the Board of Trade to introduce a complete system of food control, by regulating the importation, production, distribution, prices and quality of all kinds of food or articles necessary for the production of food. Food control actually began under this Order in Council, immediate steps being taken to lengthen compulsorily the extraction of flour (*i.e.* increase the proportion of the wheat berry which was made into flour, and so into human consumption, as against that which was left as "offals" to be used as feeding-stuffs for animals), to fix milk prices and to restrain extravagance in public meals. The Government of the day at the same time announced their intention to appoint some person with adequate authority to exercise these extended powers, in other words a "Food Controller." Before a suitable candidate for the post could be prevailed upon to accept it, the Government itself fell. The new Coalition Government of Dec. 1916 included among its novelties a food controller to whom full powers were given under a "New Ministries Act." The first holder of the new post, Lord Devonport, gave valuable support to the Wheat Commission in securing adequate tonnage and foreign credits, and carried a stage further the policy of conservation of cereals already embodied in the Output of Beer Restriction Act and the order lengthening the extraction of flour. To facilitate this the whole of the flour-mills were taken over and run on Government account as from April 1917. An appeal to the public to ration themselves voluntarily on the basis of 4 lb. of bread per head per week, 2½ lb. of meat and ½ lb. of sugar was issued in Feb. 1917, and, backed by an extensive advertising campaign, produced a definite though limited effect on the bread consumption, particularly of wealthy and middle-class households who were better able to obtain alternative foods; for the working-classes alike in industry and in agriculture the suggested ration of 4 lb. a head was impracticably low and among them the appeal met with little response. The failure of the potato crop gave trouble and a first illustration of the dangers of price fixing. Considerable thought was expended by successive committees in devising better methods for the distribution of sugar, but before any could be adopted Lord Devonport resigned (June 1917).

During the spring of 1917, the submarine menace was growing. The very possibility of feeding the people seemed to be threatened. Meanwhile, the people themselves were mainly disturbed by the rise of prices and the bad distribution of sugar. The reports of the Commissioners on Industrial Unrest, received in June 1917, emphasised these two points above all as the causes of unrest. With the coming of the second food controller, Lord Rhondda, the food problem had reached a more serious stage and was met by far more serious measures.

Lord Rhondda prepared himself and the Ministry of Food to deal thoroughly with all three aspects of supplies, prices and distribution. First he attacked prices. In Sept. 1917 the price of bread was lowered from 1s. or 1s. 1d. to 9d. for the quartern loaf, the difference being paid by the Government as a subsidy. At about the same time there was fixed a scale of prices for meat and for live stock, descending month by month from 74s. per cwt. in Sept. 1917 to 60s. in the following January. The fixing of meat and live-stock prices needed to be and was intended to be accompanied by measures for regulating slaughter and marketing, but for various reasons the latter measures did not become effective till the end of 1917. The scale of prices standing by itself gave the farmers a strong inducement to hurry on their beasts to market, so as to profit by the early high prices and avoid the later low ones; too many beasts were thrown on the market before Christmas and too few were kept for the new year; how the ensuing shortage, aggravated by large purchases of home-grown meat for the army and by other circumstances, was dealt with by rationing in the early part of 1918 is described elsewhere.

On the general principle of controlling supplies of all essential foods as a condition of fixing prices Lord Rhondda never hesitated. This policy was carried out most completely in the case of imports. Cereals and sugar were already being imported by the two commissions. Under Lord Rhondda all bacon, ham, lard, cheese, butter and similar provisions, all oils and fats (edible and otherwise), condensed milk, canned meat and fish, eggs, tea and even such extras as apples, oranges, jam and dried fruits, brought into this country, came to be directly imported by the Ministry of Food or requisitioned on arrival. All home-produced meat and cheese and most of the butter passed through the hands of the Ministry as also, through the control of flour-mills, did all the wheat and most of the barley. Even the whole potato crop of 1918 was taken over under a scheme framed in the time of Lord Rhondda, though not put into force till after his death. Ultimately 85% of all the food consumed by civilians in Great Britain was actually bought and sold by the Ministry of Food. The only important exceptions were milk, fresh fish and fresh vegetables. The total turnover of the Ministry's trading (including the two Royal Commissions) was nearly £600,000,000 a year.

Lord Rhondda made a budget of the food required for the country as a whole, and then took steps to see that that amount of food was available. This was partly a matter of securing imports; for this was needed, on the one hand tonnage, and on the other finance, that is to say, foreign credits; the Ministry of Food acting through or with the Governments concerned made bargains with the producers for the whole exportable surplus of Canadian cheese or Australian wheat or American bacon. It was partly a matter of encouraging food production at home. A vigorous food production campaign was started under the Ministry of Agriculture, and the Ministry of Food cooperated with the agricultural departments, in fixing only such prices as appeared likely to secure adequate supplies. In effect, in fixing prices for home produce, it made bargains with the farmers as to the prices at which, with whatever show of reluctance or grumbling, they would be able and willing to produce and to deliver their produce to the Ministry or its agents. The legal power of the Ministry to fix any prices it thought good was absolute; the prices for home produce were actually fixed only after apparently interminable consultations, and were prices which could be expected to produce the required supplies, and did.

The largest single source of imported supplies was the United States. Here a special department of the Ministry was established (Oct. 1917), to purchase on its behalf all food-stuffs other than cereals, for which an organization already existed in the Wheat Export Co., a branch in Toronto dealt with Canadian supplies. The department speedily grew into an international organization of vast scope; the "Allied Export Provisions Com-

mission" purchased between Oct. 1917 and Feb. 1919 nearly 2½ million tons of food valued at £267,000,000, at a cost for administration amounting to about ¼ of 1% on this turnover. All these figures exclude cereals and sugar.

The success of this policy of ensuring supplies by direct purchase abroad and consultation at home was unquestionable. The United Kingdom came nearer than any other European country to maintaining during the war a pre-war standard of supplies, and at the same time achieved a far more equitable distribution. This was due to the fact that there was a single national authority making itself responsible for looking after food supplies as a whole, and for using such influence with other departments as would secure that they were forthcoming.

Upon control of supplies was founded an even more extensive control of prices. Once goods were in the hands of the Ministry, it only remained to fix the margins of profit to be allowed to the various classes of distributors and the resulting prices to the public. This was done on the basis of "costings—" that is to say, investigation of the actual costs incurred and margins of profit required by typical distributors; effect was given to the recommendations of the Costing Department of the Ministry by statutory orders fixing the prices or the profits to be allowed at each stage. Ultimately out of everything consumed in the United Kingdom by way of food and drink, 94% was subject to fixed maximum prices. Almost the only articles untouched were fresh vegetables, canned fruits, honey, salt, vinegar, spices, aërated waters and meals in restaurants. Many of these but barely escaped, and only the Armistice prevented the Ministry of Food from fixing prices for soap and candles. It did regulate the prices of tallow, beehive sections, horsemeat and desiccated coco-nut as well as those of oil cakes and other feeding-stuffs. At the time of Lord Rhondda's appointment, many authorities were inclined to say that any fixing of maximum prices must check supply and lead to the disappearance of the article in question. Lord Rhondda secured himself against this by controlling the supply to start with and only fixing the price when the supply was assured. In one or two cases alone, of which beer and the "disappearing rabbit" are the most familiar, did he depart from this policy; he then did so more or less deliberately because it seemed more important to give the public the comfort of protection against profiteering than to ensure them the food.

Lord Rhondda died in July 1918, after a year of office as food controller and nine months of active work. His successor (from July to Dec. 1918) was Mr. J. R. Clynes, who had previously held the post of Parliamentary Secretary at the Ministry and, amongst other matters, had taken an active part in the formation and work of the "Consumers' Council"; this was an advisory body, consisting mainly of representatives of trade unions and cooperative societies, which did a great deal to keep the Ministry in touch with the feelings and grievances of working-class consumers. Mr. Clynes naturally made no great changes from the policy of Lord Rhondda. The most marked feature of his tenure of office was the development of international action, following upon a visit to Europe of the American food controller, Mr. Hoover. An Allied Food Council, consisting of the four food controllers of Britain, France, Italy and the United States, with a standing "Committee of Representatives," was established in Aug. 1918. There was thus extended to food generally the plan already in force in respect of cereals (and to a less extent sugar and one or two other articles), of making international instead of merely national programmes of food requirements, and presenting these international programmes to the financial authorities and the shipping authorities for supply if possible of the necessary foreign credit and tonnage.

By the latter part of 1918, the submarine menace had been practically mastered by the convoy system, and the limits of the food problem had been defined by the success of rationing. The greatest pinch of all, however, was apparently still to come. Considerations of shipping dictated a concentration of traffic on the shortest route—the N. Atlantic—and the abandonment so far as possible of any attempt to get supplies from the Far South and the Far East. Financial considerations by a natural reaction dictated the exact opposite; the British Treasury had relatively ample sterling credit for purchases in Australia, very few pesos in S. America and hardly a cent to spare in the United States or Canada. The Ministry of Food, and other supply departments, constantly found themselves being offered ships only where they could not get credit, and credit only where they could not get ships. On top of this standing or rather gradually growing difficulty came in Sept. 1918 the necessity, as it then appeared, of hastening the transport of the American army so as to deliver a decisive blow in the coming spring. The framing of shipping programmes had by that time reduced itself to a division of two lions' shares between the Ministry of Munitions and the Ministry of Food (or their international extensions), with a few scraps for import of raw cotton or fertilizers and the like; each of these departments was compelled to accept for the winter of 1918–9 a provisional import programme totally inadequate for its needs and to hope that the war would end before its stocks ran out.

This hope was realized. The Armistice of Nov. 11 put an end to hostilities though not to food control, or food shortage in the United Kingdom or other countries. The Ministry of Food, under two more food controllers—Mr. G. H. Roberts (from Jan. to Feb. 1920) and Mr. C. A. McCurdy (from March 1920 to March 1921), lived longer after the end of hostilities than it had done during them, and after its formal demise on March 31 1921, left a substantial legacy of work and staff to be transferred as a "Food Department" to the Board of Trade. The winding up of a business so vastly beyond the scope of any private concern and the adjustment of accounts with the accuracy required of public departments inevitably took much time. The problem of judicious de-control, that is to say of handing back to private traders the responsibility for maintaining food supplies, without risking any failure of supplies or any excessive rise of price, proved exceedingly difficult; it was complicated by more than one change of view as to the speed with which and the extent to which de-control should be accomplished. A reason for not hastening the end of food control appeared in the disturbed condition of industry and the perpetual threat of paralysis in the essential services of coal or transport. The success with which, during the railway strike of Oct. 1918, the supplies and distribution even of perishable foods were maintained by the Ministry of Food shed lustre on its declining years.

At the end of 1918 the Ministry of Food issued a short memorandum with tables and diagrams illustrating its work under the four main heads of supplies, stocks, prices and rationing.

In respect of supplies a comparison is made in the accompanying table of the amounts of the principal food-stuffs available per head for consumption in 1918 and before the war, in the United Kingdom, Germany and Holland:—

*Weekly Domestic Consumption of Bread, Meat, Fats and Sugar per Head per Week in the United Kingdom, Germany and Holland. Pre-war and 1918.*

| | United Kingdom | | Germany | | Holland | |
|---|---|---|---|---|---|---|
| | Pre-war | 1918 | Pre-war | 1918 | Pre-war | 1918 |
| | lb. | lb. | lb. | lb. | lb. | lb. |
| Bread and flour | 6·12 | 6·57 | 6·44 | 4·06 | 7·25 | 3·06 |
| Meats | 2·50 | 1·54 | 2·25 | 0·49 | 1·50 | 0·44 |
| Sugar | — | ·50 | — | 0·33 | — | 0·52 |
| Fats | 0·51 | 0·45 | ·56 | 0·15 | 0·70 | 0·37 |

The consumption during 1918 is based on the rations, except in the case of bread in the United Kingdom, where the actual consumption is taken. In the case of sugar no figure of pre-war domestic consumption is given by the Ministry of Food; it is commonly estimated at about 1 lb. per head per week.

It appears from the table that in 1918 the United Kingdom "had half as much bread again as Germany, three times as much meat and fat, and substantially more sugar. As compared with Holland, the United Kingdom had twice as much bread, three times as much meat, more fats, and practically the same amount of sugar." In comparison with pre-war consumption, the bread consumption per head in the United Kingdom had actually increased slightly in 1918; fats had fallen very little; meat had fallen by a little over a third; sugar had fallen somewhat, but

an exact comparison was impossible. In all cases the deficiency in 1918 on pre-war figures was far greater, both for Germany and for Holland. In respect of stocks, the figures show how at Sept. 1 1916 wheat, fats, meat and sugar were near the pre-war level, "a dangerous point in war, having regard to the uncertainties of transport," and by Sept. 1918 had been built up to a level ensuring safety for the coming winter.

The course of prices is shown in two stages; one from July 1914 to July 1917, when the main development of food control in the United Kingdom began, and the other from July 1917 to Oct. 1918. For each of these periods the course of British food prices is contrasted (*a*) with that of the prices of certain other staple articles (textiles, coal and soap) in the United Kingdom; (*b*) with that of food prices in France, Germany and Sweden, respectively:—

*Rise in Price of Food and Other Necessary Articles in United Kingdom.* (*Price in July 1914 = 100.*)

| | July 1917 | Oct. 1917 | July 1918 | Oct. 1918 | Average monthly increase between July 1914 and July 1917 | Average monthly increase between July 1917 and Oct. 1918 |
|---|---|---|---|---|---|---|
| Principal controlled foods | 205 | 194 | 202 | 216 | 2·92 | 0·73 |
| Principal controlled foods assuming no subsidy on bread | 205 | 205 | 208 | 232 | 2·92 | 1·86 |
| Principal uncontrolled foods | 186 | 229 | 311 | 347 | 2·39 | 10·73 |
| All principal foods | 203 | 198 | 213 | 229 | 2·87 | 1·73 |
| Textiles, leather, etc. | 234 | 245 | 294 | 313 | 3·72 | 5·27 |
| Coal | 135 | 135 | 163 | 177 | 0·97 | 2·80 |
| Soap | 133 | 150 | 233 | 233 | 0·92 | 6·67 |
| Candles | 184 | 184 | 329 | 348 | 2·33 | 10·93 |
| Household oils | 215 | 286 | 319 | 319 | 3·20 | 6·93 |

*Comparison between Prices of Bread, Beef, Butter and Milk, in the United Kingdom and in Other Countries.* (*Price in July 1914 = 100.*)

| | July 1917 | Oct. 1917 | July 1918 | Oct. 1918 | Average monthly increase between July 1914 and July 1917 | Average monthly increase between July 1917 and Oct. 1918 |
|---|---|---|---|---|---|---|
| United Kingdom | 185 | 179 | 179 | 195 | 2·36 | 0·67 |
| France | 170 | 160 | 203 | 220 | 1·94 | 3·33 |
| Italy | 149 | 154 | 255 | 264 | 1·36 | 7·67 |
| United States | 140 | 148 | 153 | 161 | 1·11 | 1·40 |
| Sweden | 160 | 178 | 268 | 305 | 1·66 | 9·67 |
| Switzerland | 180 | 187 | 213 | 215 | 2·22 | 2·33 |
| Germany | 181 | 201 | 249 | 228 | 2·25 | 3·13 |
| Austria | 318 | 367 | 502 | 622 | 6·05 | 20·27 |

The following comments from the memorandum of the Ministry of Food are interesting:—

"The effect of the introduction of price control from July 1917 onwards is very marked. The rate of increase for controlled food since that date is one-quarter of the rate before then and is also very much less than the rate for other articles and for other countries. If the prices of such food had continued after July 1917 to rise at the same rate as before, they would in Oct. 1918 have stood not 115% but 150% above the pre-war level. If they had continued after July 1917 at the same rate as textiles, they would have reached 185%. The controlled foods cover 94% of the total food expenditure.

"The keeping down of food prices is of course to some extent due to the introduction of the bread subsidy. Though with this allowance the effect of control in slowing down the rise of prices is naturally less, it is still clearly marked. The rate of increase in food prices after July 1917 remains little more than half the rate before then, and less than the rate of increase for any of the other articles shown. To this result two distinct factors have contributed—one, the fixing of prices and margins by the Ministry of Food on a costing basis in this country; the other, the action of the Government of the United States and other exporting countries in controlling the prices paid to the producers there.

"It is probably no exaggeration to say that a large part of the population have been better fed during the war than at any previous period, because for the first time they have been assured of regular work and wages. A number of luxuries and subsidiary foods—fruit, canned fish, sweets, etc.—have been cut off. The supply of essential foods, though reduced as a whole, has been sufficient for all because it has been fairly distributed among rich and poor."

The Ministry of Food in the United Kingdom accomplished, with a reasonable minimum of mistakes, the work for which it was established. The rationing system adopted is dealt with separately under RATIONING. Two cautions or criticisms are not out of place. First, the administrative machinery required was very extensive. The staff directly employed by the Ministry, either at headquarters or in the offices of the Divisional Food Commissioners and Livestock Commissioners, numbered at its maximum over 8,000. In addition the local food control committees employed varying numbers, rising at times of exceptional pressure to as many as 25,000 persons. The printing and stationery bill for a single year exceeded £1,500,000. The expenditure was no doubt fully justified by results, and under the arrangements made it did not fall on the taxes but was covered by a trifling percentage on the price of the articles in which the Ministry dealt. Second, while the profits and margins secured by distributors were undoubtedly lower than they would have been in a time of scarcity without control, they were probably not as low as in a time of plenty without control but with competition. The policy was adopted, indeed no other policy was possible, of preserving the normal channels of trade. This meant that the margin at each stage of distribution, *i.e.* the difference between the price at which the distributor received his supplies and that at which he was compelled to pass them on, had to be fixed at a point which would afford a living to the distributor of average or less than average efficiency. The more efficient distributor could still make very large profits and did so; he had no motive for cutting prices in order to increase business, since his share of the total business was stereotyped.

If the position of the United Kingdom be briefly compared with that of other countries, it is seen that the central fact facilitating food control in the former was that it had to look to imports rather than to home production for the bulk of its supplies. This simplified the problem of the British food controller (till he was driven to rationing) by making it largely a question of how much shipping he could extort from the shipping controller and how much foreign credit from the Treasury. Both Italy and France produced a larger proportion of their cereals at home, and required less meat. In Italy even sugar was mainly home grown. For the food controllers of Central Powers, questions of importation hardly arose. Their main problem—and one which they solved only to a limited degree—was that of inducing the farmer to give up a fair proportion of his product at the official price to the public authorities. They seem, indeed, to have been considerably less successful than the British food controllers in getting agreement with the agricultural population on production and prices; sometimes, at least, prices were fixed which the farmers regarded as arbitrary and which they evaded systematically by contraband sales. Two minor features may be mentioned as having simplified the British task. One is the concentration of the great bulk of flour-milling in the United Kingdom in a small number of important mills (less than 700), which could be readily controlled and which furnished the only easy market to the farmer and the corn merchant; in most other countries mills are more numerous and smaller, and it is common for the farmer to grind his own corn. The other is the limited power of the British municipal authorities. In Germany it was the natural thing for the separate municipal councils to act as independent organs of food control, making their own contracts with neighbouring rural districts for the supply of food to their citizens, fixing prices in their markets, and rationing when need arose. This made possible competition, confusion and difference of standard between the authorities, and made difficult a survey of the nation's needs and resources as a whole. In the United Kingdom, Lord Rhondda, as housekeeper for a family of forty millions, made a single bargain with each group of producers, put all the supplies from different sources into one pool, and distributed them fairly at standardized prices.

In the United States (see p. 98) the problem was different. That country in itself experienced no shortage of any essential food, but became the great source of supply to all the Allies in Europe, and gained in importance as shipping was concentrated

on the shortest and most defensible N. Atlantic route. To perform this function it applied (1) a great food production campaign, (2) a campaign for voluntary food saving in order to leave a surplus for the Allies. It had then to face the administrative problems of getting these supplies along the railways and through the ports in competition with munitions, and with its own army. (W. H. B.)

### Feeding of the British Army During the War

The feeding of any army is a feature of the Supply Department, the term "supplies," from a military point of view, being applied to all stores and articles required for the maintenance of an army in the way of food or fuel for men, forage for beasts, or fuel, petrol and oil for aircraft or mechanical transport, hospital requirements in the way of food, medical comforts, etc., with the exception of medicines, drugs or surgical appliances (*see* generally Supply and Transport).

For a proper understanding of the problem of feeding a modern army, and of what was done in this connexion by Great Britain during the World War, it is necessary to recall how armies were fed in the past. In primitive times, when one nation or tribe invaded another, the subsistence of an invading army depended upon indiscriminate individual plunder. The process was so wasteful that this individual plunder was soon supplanted by a more economical system of gathering the spoil into heaps or magazines; but accumulation is but a means to the end of distribution, and in return for such distribution of victuals a deduction or stoppage was soon made from the pay of the soldier. This was the beginning of the financial control of the department of supply. The third stage was to organize plunder more thoroughly by compelling inhabitants to form magazines, or in other words, by recourse to requisition. The fourth stage was speedily reached by its being discovered that such magazines were more readily and effectively created if the inhabitants were paid instead of compelled to fill them; thus for robbery was substituted purchase, and instead of the military hand was substituted the financial hand, and the hold of the Treasury over the province of supply was strengthened. As the means of communication improved, the mobility of armies called for a better organization of supply. It became imperative to import foodstuffs from a distance, as, owing to the growth of armies, the theatre of war was no longer able to maintain them from its local resources. To bring food from a distance requires transport, and consequently the Treasury or civil side were gradually obliged to organize a transport as well as a supply system. In military operations, the maintenance of order on roads, and means of communication, are of first importance, and order cannot be maintained without discipline. Transport therefore very early passed under the military or semi-military control, whereas supplies remained much longer under civilian or Treasury control, with the result that there was constant friction.

For two long centuries in Great Britain the Treasury struggled against the concession of any financial powers to any military department, and as a consequence, untold millions of money were wasted; only in 1888 the two Departments of Transport and Supplies were blended into one and placed upon a military footing by the creation of the Army Service Corps, thus bringing these two important services completely and entirely under the commander-in-chief, or as it is to-day under the Army Council.

What might be described as the first systematized endeavour to feed British troops in the field was introduced during the wars in the Low Countries. The Treasury appointed a commissary, who was invested with supreme financial control, and was responsible for the maintenance of the army. His system of going to work was to make a contract with some individual to supply the army with bread and bread waggons, and with the supply of this article his responsibility for the feeding of the army came to an end; all other provisions were a regimental matter and were furnished by private speculators, namely, victuallers, sutlers and butchers. This system of contracting practically continued, with slight if any modification, right down to the outbreak of the World War, with considerable modifications, of course, as the centuries and years passed, so far as the soldier's ration was concerned; meat was added first, and bread and meat formed the sole ration issued free to the troops in England up till towards the end of the 19th century, when during peace-times a soldier got a money allowance in addition, for the purpose of buying the remaining portion of his rations.

During the ordinary peace-times, and before the outbreak of the World War in 1914, the system in force in Great Britain as regards the feeding of the army was by means of contracts. The General Officers holding the chief commands made arrangements by periodical contracts, varying in duration from anything to 3, 6 or 12 months, for the supply of commodities required.

The soldier was supplied with his bread ration 1 lb., his meat ration ½ of a lb. He was credited personally with 3d. per diem. This sum was supplemented in a well-run unit by an additional grant of ½d. or so from the canteen funds; the money was expended in the Regimental Institute on the remaining portion of the soldier's food, *i.e.* groceries, vegetables, extra dishes, etc.

In war-time the entire maintenance of the soldier became the duty of the State, so that from providing only two articles, bread and meat, the State was faced with the problem of providing a complete and full diet, consisting of a very large number of articles and other requirements.

In order to fulfil these duties, the system in the past had been for the War Office to enter into a number of contracts with numerous army contractors for the supply of the various goods required. The contractors would undertake to supply so much biscuit, cheese, jam or any other of the many and various articles, either delivered at the base of operations abroad, or more frequently on board ship at a port of departure in this country. In order to insure that the requisite quality of the goods was kept up, a number of (generally speaking, retired) officers were appointed to carry out periodic inspections at the factories or other places of production. It will be readily seen that such a system was bound to lead to grave abuses, and at the termination of every war up to that of 1914–8, there had always been either grave complaints or scandals, necessitating an enquiry as to why the troops were supplied with bad food, and frequently as to why the State was swindled.

In the event of a general mobilization, the laid-down scheme or plan was that so far as the Expeditionary Force was concerned, the War Office would enter into contracts for the supply of the necessary articles required; the supply of meat being insured by employing contractors to drive live cattle behind our army in the field, and all other supplies to be obtained as explained above For the feeding of the troops mobilizing or being trained at home, general officers and commanders-in-chief were to make their own arrangements in the way of entering into contracts to meet the requirements of their troops, and this system was practically the same as had been approved and agreed on ever since any proposal for general national defence had ever been considered.

Early in 1909, the British War Office, having received information as to the rapid mobilization plans for the German army, decided that it would be necessary to increase the rapidity of British mobilization, and with this end in view, instructions were issued for considerable acceleration. Up to that time it had always been considered that it would be quite impossible for any Expeditionary Force to leave Great Britain in under three weeks, whereas under the new proposed scheme it was suggested that the larger portion could be in a position to depart almost in as many days. In order to carry out these proposals, it was of course necessary to accelerate considerably the supply mobilization machinery. There was at Woolwich Dockyard an accumulation of preserved meat, biscuit, tea, coffee, sugar, jam, salt, medical comforts, etc., sufficient for the requirements of the Expeditionary Force for a few days. The proposal then was that, by means of urgent priority telegrams, army contractors would be got into touch with, and arrangements made for all supply requirements at the earliest possible moment.

In July 1909, Col. (later Maj.-Gen.) S. S. Long (b. 1863), on vacating the position of Commdt. of the A.S.C. Training Establishment at Aldershot, was posted as Assistant Director of

Supplies at Woolwich Dockyard, and on assuming charge there he found that the total written instructions as regards supply mobilization in the event of war were embodied in some three or four typewritten sheets of foolscap, the bulk of the instructions being little more than pious hopes. Up to that period, Col. Long (who, having been through the S. African War, had in that war become D.A.A.G. and then A.A.G. for transport) had been looked upon at the War Office as a leading transport authority, he having compiled the official text-book upon this important subject. He proceeded to make a close study of the whole supply problem, with the result that he gradually evolved a new system for the feeding of the British Expeditionary Force. This system was put into operation from the outbreak of the World War to its termination, without being in any way materially altered. Instead of the costly and wasteful way of obtaining and driving live cattle for the purpose of meat supply, behind the armies, he proposed that frozen-meat ships, loaded up with tens of thousands of carcasses of sheep or quarters of beef, be placed at convenient ports, and from these ships the fresh meat supply would be absolutely guaranteed, and at a cost very slightly above the usual price pertaining during peace-times, and much less than half what it had cost in any previous war. The frozen meat ships not only fulfilled the purpose of insuring the meat supply, providing an adequate reserve of from 50 to 60 days at a time, but they also served a further purpose of acting as cold storage for quantities of hospital supplies, such as fish, poultry and many other commodities required for the invalid feeding of the many sick and wounded.

The original supply mobilization proposals presupposed army bakery companies, moving immediately behind the troops and baking bread to meet the requirements. In the S. African War of 1899–1902, similar arrangements had been made, but actual practice had proved that it was impossible of fulfilment, and the bulk of the British troops were then almost entirely fed upon the much-disliked army biscuit. Col. Long now suggested that the more feasible and sound plan was to locate the army bakeries a long distance in the rear of the fighting troops; that the loaves of bread as baked should be put 50 at a time into the cheap, loosely woven sacks which are readily and plentifully to be obtained in the trade at comparatively small cost, known as offal sacks, and by this means they would be readily handled and railed forward daily to the troops right into the fighting line. His recommendations and their adoption were proved quite correct, with the result that for the first time in its history, the British troops were during the World War fed largely on bread instead of biscuit, in spite of the vast numbers under arms. Instead of the old system of contractors putting the goods they had contracted to supply on board ship, or delivering overseas, Col. Long suggested that a definite home port should be selected as the spot from which all supply requirements for the army would be despatched, to be known as "The Home Base Supply Port," and after consultation with the Admiralty it was finally agreed that Newhaven should be earmarked for this purpose. It was then arranged that directly on the outbreak of war, an already earmarked staff in the way of Naval Embarkation Officer and officer in charge of the Supply Depot, with all the necessary staffs, etc., would instantly proceed to this port, taking over all the available stores, and generally carrying out the duties of such a port, whilst all contractors would consign their goods to that port, where they would be thoroughly examined and passed as sound and fit to be embarked on the various supply ships. In order further to protect the public and the soldier's interests, arrangements were made with the Public Analytical Department of Somerset House, for that department to send a staff of chemists down to Newhaven to analyse the goods on the spot, so as to save time; and it is only right to emphasize the debt of gratitude due to the Analytical Department for insuring not only that the goods were of the proper quality, but also that the fighting soldiers were adequately fed.

During the years that followed from the end of 1909 onward to 1912, the schemes and plans to be adopted in the event of a general mobilization and the despatch of the B.E.F. were gradually elaborated and extended, until at the end of 1912 all supply requirements had been most fully thought out and provided for, together with complete instructions for the Home Base Depot, the overseas depots, etc. Nothing remained to be done in the event of mobilization beyond putting the scheme in force.

Meantime, Col. Long had been evolving schemes for the modernizing of the feeding of a nation in arms, which he foresaw must result in the event of a great European war, involving general mobilization. However, at this period—although directly under the War Office, not being a member of the War Office staff—he found little opportunity of ventilating his opinions or successfully bringing his suggestions to notice. In Jan. 1913, Gen. Long moved from Woolwich Dockyard into the War Office becoming Director of Supplies. He then set to work to inaugurate an entirely new system, the essence of which was the complete elimination of contractors with the British forces either in the field or at home. Except in a very minor degree as regards home forces, everything required for the forces would thus be obtained direct from the factories, so that the middleman's opportunity had disappeared.

Up to this time it had been left to individual generals, commanders-in-chief, commanders of district or coast defence, to make their own arrangements and contracts, so far as feeding and forage were concerned, with the result that in the event of war occurring, there would have been a very large number of authorities going on the general markets of the country, and purchasing not only against the public, but against each other. This old system, in circumstances such as those at the outbreak of the World War of 1914, would have undoubtedly created a veritable Eldorado for the unscrupulous contractor, who would thus have been enabled to make vast fortunes; and there is very little doubt that, had the old system continued, a very much worse question would have arisen owing to the uncontrolled purchasing by a large number of authorities, since in addition to those named above, the War Office itself and the Admiralty would also have been heavy buyers, and a panic would undoubtedly have occurred on the market. Furthermore, under such a system, it would be absolutely impossible to move troops in large bodies from one part of the country to another.

Gen. Long pointed out that only one system was possible or would insure safety, and that was for one Government department under one individual alone to be responsible for all army maintenance. According to his proposals, it was suggested that three great base depots be formed, one in London, one at Bristol and one at Liverpool, and that in addition, a number of main depots be created, one at Glasgow for the supply of Scotland, one in Dublin to meet the requirements of troops in Ireland, and three down through the centre of England, at Leeds, Northampton and Reading; the idea being that at each of these great depots—at which cold storage was available—would be accumulated sufficient reserves of rations of all kinds to meet the requirements of so many hundred thousand men for a given number of days, so that when it became necessary to move large bodies of troops in any direction desired, all that it was necessary to do was to increase automatically the reserves of the depot affected by the number of troops based thereon; the War Office being entirely responsible for the provision of these depots. The general proposal was that each of these proposed depots should be very carefully surveyed, all plans and arrangements drawn out, together with the necessary establishment of officers and other personnel. Standing orders and full instructions would be prepared for each depot, so that, in the event of being required, everyone connected therewith could step into their place with the minimum of confusion. Then, should occasion arise, for the first 10 days after mobilization was ordered the depot would not be called upon to perform any duties other than organizing itself and receiving the supplies which would be poured into it, under arrangements to be made centrally by the War Office. Meanwhile at the War Office itself would be kept not only full details of each depot, but a consolidated return showing the total requirements, so that directly mobilization was ordered the Contract Branch of the War Office, working

under the instructions of the Director of Supplies, would at once proceed to make the necessary contracts to purchase the supplies required to meet the needs of each particular depot. Under the old system it was, of course, obvious that, in the event of a general mobilization, the ordinary contract system of feeding the troops in the United Kingdom would necessarily break down, owing to the fact that at many of the stations the contractor would possibly be only a small butcher or baker, supplying depots of possibly one or two hundred men in number, whereas on mobilization that same depot at once expanded into several thousand, entirely beyond the ordinary small contractor.

Gen. Long's proposal for dealing with this matter was that on mobilization, as all contracts failed, and owing to popular excitement, possible inflation of prices, etc., it would not be possible to make other satisfactory contracts, every commanding officer would be authorized to take credit in his regimental messing accounts for 2s. for every man present with or joining the unit under his command, and similarly the sum of 1s. 9d. per diem per horse, and that he was then to make the best local arrangements he could with the money in question for the feeding of his men and animals. This system would go on for 10 days. At the end of that period the great depots throughout the country would be stocked and in working order and ready to take up the whole army supply throughout the United Kingdom.

These ideas were so novel and completely at variance with the general accepted ideas of the past, that when Gen. Long first made these proposals, they met with determined opposition from the finance side of the War Office. It was not indeed till July 1914 that he succeeded in getting his way and forcing the civil side of the War Office to accept his proposals, and it was not until towards the end of that month that the final instructions to all commands went out, directing exactly what was to be done in the way of feeding men and animals on mobilization. Similarly he met with strong opposition to his proposals for the formation of the great depots, not only from the civil side of the War Office, but also from the military as well.

Incidentally this complete change of system of army supply, and entire departure from all the laid-down rules of army feeding of the past, successful as it was from an army point of view, was if possible of even greater importance to the nation at large. Had the old system continued and been in operation when the war broke out, every army contractor, and every trader who aspired to be such, would instantly have proceeded to buy up the market and corner the various commodities, in the hopes of selling them at a great profit under contract to the various generals seeking to make contracts for the feeding of the troops under their command. As a matter of fact, in a measure this did happen on the outbreak of the war, so far that holders of goods and commodities withheld their stocks and ceased to put them on the market. Immediately after the outbreak of the war, it suddenly became impossible to buy a number of household requirements in the way of sugar, bacon, etc., owing to there being none on the market; well-to-do people, in a panic, began to lay in stocks at exorbitant prices, and from many large towns came the sounds of ominous murmurings from the poorer population who were unable to obtain their daily food. This continued for some three or four days; and it was not generally realized that it was the adoption of Gen. Long's system that suddenly restored an absolutely free market, with commodities little if anything above the prices prevailing at the end of July 1914. The reason for this was that the War Office being the sole buyers, and finding that importers, manufacturers and holders of goods were refusing to sell, Gen. Long, without waiting for authority, and taking the law into his own hands, proceeded to requisition certain requirements urgently wanted by the Expeditionary Force. He thereby forced the Government to pass immediately a requisitioning Act, and within 24 hours the holders of commodities were throwing their goods on the market, fearing to hold lest they should be requisitioned. Also, the War Office being the only buyers of meat other than the ordinary public, they were in the position of forcing the meat market to continue reasonable prices under the threat of requisition if they failed to do so. This close control over the meat market was practically maintained right up to the middle of 1916, when the price of good average quality frozen meat to the Government landed in England was only a decimal point or two over 6d. per pound, and to the public at large only some couple of pence more.

During peace-time, in order to insure that the quality of supplies composing the soldier's ration should be kept up to a good sound standard, all A.S.C. officers were carefully trained so as to be good judges in this respect, and in addition, some exceptionally well-qualified officers were appointed special inspectors. On the outbreak of war, of course, all such officers were necessarily required for the fighting formations or for other almost equally important duties in connexion with the mobilized armies, and consequently the general inspection of supplies as to quality had to be relegated to a number of retired officers. The result of this in the past had been that, although such officers did their best, many of them had been retired for a great number of years, and were entirely out of touch with modern requirements, or, owing to age or infirmity, the work required was beyond their capabilities. The day following the outbreak of the World War, Dr. MacFadden, the medical head of the Public Health Department of the Local Government Board, went to Gen. Long at the War Office, to know if he could be of any assistance to him. Gen. Long at once replied that there was no one who could do more for the country and the soldier than the Local Government Board if they would undertake the duties; he was well aware that, under the procedure adopted by great Government departments, opposition would be raised by the Military Medical Authorities and the War Office, to the idea that the Local Government Board should in any way be allowed to interfere with the food of the soldier or the methods of its supply, etc.; but he for his part could not devise any system for a proper inspection, whereas the Local Government Board had all machinery ready to its hand, which could be turned over for the protection of public interests, and also the soldier's, without it costing one single penny. Gen. Long therefore proposed to Dr. MacFadden that he (Dr. MacFadden) should undertake the entire responsibility of seeing that all foodstuff supplied for use of the soldier should be of unexceptional quality, thoroughly sound and good, and fully complying with all the conditions of purchase; that he himself (Gen. Long) would supply Dr. MacFadden with copies giving specifications of everything in the way of food-stuffs; he would also supply Dr. MacFadden with a list of every factory, warehouse or other persons supplying the War Office with food-stuffs throughout the United Kingdom, and keep him so supplied; and then, if Dr. MacFadden would supply to each Health Officer a copy of the specifications and a list of the premises where food was being stored or manufactured for the War Office within that Health Officer's area, and request him to keep the closest watch upon the same, and immediately to take action under the Public Health Acts, if any wrong were committed or attempted—then a perfect system of inspection would be attained.

All these duties Dr. MacFadden readily undertook, and the result exceeded the most sanguine expectations. The prosecutions were singularly few, but this undoubtedly was largely due to the closeness of the inspection. Medical Officers of Health threw themselves whole-heartedly into the scheme, and not only visited factories daily, but posted their inspectors of nuisance almost continuously on the premises. As a result of the first prosecution, a letter was sent to the Medical Officer of Health for the district in question, by Gen. Long on behalf of the Army Council, thanking him for his public services in safeguarding the interests of the country and more particularly the interests of our fighting men. The result of this was that every Medical Officer of Health throughout the United Kingdom redoubled his efforts to insure the best of quality, in the hopes that, could he catch a supplier slipping, he would then have the good fortune to obtain a similar letter. It is a well-known fact in official life that one Govt. Dept. objects to giving credit to another department for any work which it may do, and consequently it is not to be wondered at that little or no acknowledgment was made

by the War Office for the services which were performed for them by the Local Government Board in general, and Dr. MacFadden and all his officers in particular. The Local Government Board also undertook to send specially qualified Health Officers abroad to see that the quality of preserved meat being manufactured in both the United States and S. America was kept up to the highest possible standard.

It is unnecessary to go in detail into the very slow but gradual improvement of the soldier's ration in war. The appalling mistakes and lack of suitable feeding for the British armies during the various modern campaigns from the Napoleonic wars down to the outbreak of the World War can in a large measure be read in the various histories of those wars. The starvation and neglect of the armies in the Crimea are well dealt with by Kinglake; but although Great Britain had been involved in a great number of minor wars, the authorities still seemed to lack the power of organizing our supply service upon a proper basis. To take only two campaigns to exemplify the fact:—the Egyptian War caused many complaints and grumblings as to the unsuitability or lack of proper food, and the heavy cost of the same, although at that period the improvement of the soldier's diet was greatly in advance of previous campaigns; S. Africa showed still more improvement, but owing to the lack of system it was a frequent complaint that the supplies on arrival at the front were in a rotten and putrid condition—there were many instances of their arriving in that condition at the base of operations at Cape Town or other ports. The cost was out of all proportion to what it should have been. Great fortunes were made by unprincipled contractors, and at the end of that war a lengthy enquiry was held into many grave irregularities.

Shortly before the outbreak of the World War, some experiments in food values had been carried out in America, and under War Office orders similar experiments were carried out in England. A special committee was appointed by the War Office to go into the whole question, and to recommend a suitable "active service" diet for the soldier. The result of this committee's labours was that a very carefully balanced diet was got out, which would be not only palatable, but also would contain all the necessary calories or energy units sufficient to maintain the normal man exposed to the rigours of a bad climate on active service. The recommended daily ration for the soldier on active service was as follows:—

| | |
|---|---|
| Bread—1¼ lb. or biscuit 1 lb. or flour 1 lb. | |
| Meat— | |
| Fresh, if obtainable | 1½ lb. |
| Preserved | 1 " |
| Bacon | 4 oz. |
| Meat extract (part of iron ration) | 1 " |
| Cheese | 3 " |
| Fresh Vegetables, when available | 8 " |
| Or peas, or beans, or potatoes, dried | 2 " |
| Tea | 5/8 " |
| Jam | 4 " |
| Sugar | 3 " |
| Salt | ½ " |
| Mustard | 1/80 " |
| Pepper | 1/80 " |
| Limejuice | 1/320 gal. |
| Rum | 1/64 " (At discretion of G.O.C. on recommendation of medical officer.) |
| Tobacco | 2 oz. a week. |

This ration undoubtedly gave universal satisfaction. The only improvement that it contained over that supplied to troops in S. Africa was the addition of the 4 oz. of bacon and 3 oz. cheese; but the really great improvement was that the quality was invariably well maintained, and the soldier received the same with the utmost regularity.

During the last week in July 1914, the officers who were earmarked for the command of the eight great supply depots in the United Kingdom attended at the War Office under instructions which had been issued some few weeks earlier, and before the imminence of the outbreak of the war had ever occurred to anyone, in order that as a precautionary measure they might receive some general instructions as to the new method of feeding the army on mobilization, and in order that they might then visit the actual spot where they would be employed in the event of the necessity arising, so as to be thoroughly *au fait* with the whole position so far as they were concerned. This visit to the War Office was certainly well-timed, so that after the whole of their duties had been fully explained to them by Gen. Long, they at once proceeded to their war stations, and as a consequence, on Aug. 4 1914, they had already had some few days to work out their preparations locally.

On Aug. 5, so perfect were the supply arrangements, that many trains had already been loaded and were on their way to Newhaven; the necessary Supply Officers and personnel crossed on that day to France; and on Aug. 6, two days after the declaration of war, British supply ships were already steaming across the Channel, actually preceding the troops by some hours.

The Director of Supplies, Expeditionary Force, attended at the War Office the day following the declaration of war, when he received not only printed instructions, which had been most carefully prepared as regards his own duties, but copies of instructions for Supply Officers of base depots, rail depots, advance depots and for all Supply Officers doing duty with formations.

From the moment the Expeditionary Force left, the Director of Supplies Overseas was in close daily correspondence with the Director of Supplies at the War Office, so that, as a matter of fact, the latter officer kept his hand upon the feeding of the army down to the very smallest particular.

Under a good system it is comparatively easy to maintain an army when it is victoriously advancing, but the great test of war is the maintenance of an army in retreat. If proof were ever needed as to the perfection of the supply arrangements, it is in the fact that during the British retreat to the Marne, so far as the official records go, there was only one occasion when a division went a day without its food, and was compelled to fall back on the emergency ration, consisting of 1-lb. tin of preserved meat, 1 lb. biscuit done up in a small linen bag and a grocery ration, and even on the one occasion when the division missed its daily supply of full rations, it was not the fault of the Supply Units of the Formation, but owing to bad staff work, as it was subsequently found that there were supply columns looking for this division on its right, on its left and even between it and the advancing Germans. When the forces in France were joined by divisions of native troops from India, there was a breakdown of the Indian Military Supply system; the War Office took up the duties, and never in its history had native troops been so well fed and looked after.

When it became necessary to send an expedition to the Dardanelles, and later on to Salonika, then to E. Africa, the supply system was expanded to meet requirements with apparent ease. The system, as laid down and provided for, continued in existence throughout the whole war in all theatres of operations, with the exception of Mesopotamia, which was under the Indian Government, and which, as is well known, hopelessly broke down; whereas Gen. Long's system remained in force from start to finish with but the very slightest modifications.

The business of supply being officially part of the quartermaster-general's department, at the head of which, during the World War, was the late Gen. Sir John Cowans, it must be recollected that, so far as the Expeditionary Force was concerned, Gen. Long's proposals had been agreed to during the earlier period when Gen. Sir Herbert Miles was quartermaster-general. As regards the general regulations for supply mobilization introduced by Gen. Long in 1913, Sir John Cowans was then quartermaster-general, but it is only right to say that there was not a single detail of the work which originated from him, and the greater bulk of it was carried through without even his knowing exactly what was being done. There are War Office minutes in existence, in which Gen. Cowans himself acknowledged that, so far as the supply system was concerned, during the first 10 months of the war—at the end of which Gen. Long, knowing that it was running smoothly, left the War Office—he had never in any way interfered therewith.

The crowning success of the whole British Supply system during the World War is undoubtedly the fact that not only were the troops, in spite of their great number, the best fed that the world has ever seen, but from a cost point of view possibly the cheapest fed, considering the enormously inflated world prices; and throughout the whole course of the war, for the first time in British military history, there was a complete absence even of rumours of corruption in connexion with the feeding of the army.

(S. S. L.)

UNITED STATES

Upon its entry into the World War, the U.S. Government was confronted with the fact that the previous heavy demands upon the country's markets had drained the grain reserves and diminished other important basic stocks, such as the number of breeding hogs. This situation was aggravated by the fact that the 1917 wheat harvest was far below normal and the corn crop failed to mature properly. The Government therefore found food control one of the first of its war problems. This control required measures which, without unduly disturbing the normal economic conditions within the country, would (1) increase American exports, particularly of breadstuffs, meats, fats and sugar; (2) maintain such stability in prices as would encourage the domestic producer and thus increase production, while protecting domestic consumers against speculation and profiteering; (3) regulate the distribution of food exports and imports so that only the necessary minimum should go to neutrals, that the maximum should be properly divided among the Allies, and that leakage to the enemy should be prevented; (4) enable the Government to regulate buying in the home markets so as to further all these policies.

*The Government Agency for Food Control.*—To give the executive branch of the Government the necessary powers, Congress passed as war measures the Embargo Acts (June 15 1917 and Oct. 6 1917), the Food Control or Lever Act (Aug. 10 1917) and the Food Survey Act (Aug. 10 1917). The Embargo Acts gave control over imports and exports, with power to license and fully regulate export and import operations. The Food Survey Act gave additional powers to the Department of Agriculture to enable it more effectively to assist the farmers.

The Lever or Food Control Act conferred upon the President the following powers:—(1) To license those engaged in the importation, manufacture, storage or distribution of foods or feeds, and to issue rules and regulations governing such licensees (retailers doing less than $100,000 business annually being especially exempted from this provision); (2) to buy and sell wheat, flour, meal, beans and potatoes; (3) to requisition foods and feeds for the army and navy and for public uses connected with the common defence; and (4) to create agencies for carrying out the purposes of the Act. The Act also prohibited under severe penalties the hoarding of foods and feeds, or their destruction for the purpose of enhancing their price, or conspiracy for that purpose. Other practices such as making excessive charges for foods or services in connexion with foods were made unlawful, but no penalty was provided. The Act gave no powers for price-fixing, but Congress itself fixed a minimum price of $2.00 per bus. for the 1918 crop of wheat, and gave the President power to fix minimum prices for subsequent wheat crops.

By executive order of Aug. 10 1917, the President created a governmental agency designated the U.S. Food Administration. This order appointed Herbert Hoover, food administrator, and delegated to him the powers granted to the President by the Food Control Act. Mr. Hoover, since the outbreak of the war in Europe, had been chairman of the Commission for Relief in Belgium, where he had demonstrated his ability as an economist and organizer and gained unrivalled experience in war-time food problems. The Government had called him home soon after the United States entered the war in order that he might give his advice as to the measures to be taken.

The Food Administration had thus become, by Act of Congress and executive order, the special war agency of the Government for food control. Although it worked in coöperation with the Department of Agriculture, it was a distinct agency, and the food administrator was responsible directly to the President. Because it was a war emergency agency, the food administrator could arrange that those who were associated with him in the direction of the work should, like himself, serve without compensation. As volunteers they could without reservation seek the voluntary coöperation of households, farmers and the food trades, and upon such coöperation the achievements of the food administration were principally based.

With the approval of the governor a federal food administrator was appointed in each state and territory, and he, in turn, selected a local administrator in every county and large city. In all, some 8,000 volunteers gave their whole time to the work of the Administration, and part-time service was given by some 750,000 members of the various committees, chiefly women. About 3,000 persons, chiefly clerks, received salaries. Two great governmental corporations were also created to assist the Food Administration. The first of these was the Food Administration Grain Corp. (which after July 1 1919 became the U.S. Grain Corp.), which eventually was given a capital of $150,000,000. This corporation acted as the buying and selling agency for the Government chiefly in the matter of wheat control, though it dealt to some extent in practically all the commodities in which the Government was authorized to deal by the Lever Act. The other corporation was the Sugar Equalization Board, capitalized at $5,000,000, and authorized to coöperate with the Allies in the purchase of sugar. It was through the Sugar Equalization Board that the distribution of the 1918 and 1919 sugar crops was controlled.

*Food Conservation.*—The problem of increasing American exports involved the reduction of both the waste and the consumption of all commodities, and the substitution at home of certain surplus commodities for those particularly required abroad. This was the basis of the appeals for food conservation, which became the most familiar incident of food control. The European Governments had adopted rationing (*see* RATIONING) as the basis of food conservation. Mr. Hoover and his associates, however, relied chiefly upon the spirit of self-sacrifice of the American people for this war service, and in America conservation was achieved mainly by the voluntary action of individual citizens, stimulated and directed principally by influential women who volunteered their services. With the coöperation of the entire press, an intense educational and patriotic appeal for conservation was made throughout the country. Days which became popularly known as "less" days were established. One day of the week was designated by the Food Administration as that on which a certain important food should not be served or eaten; for example, there was in each week a meatless day, a porkless day, and more than one wheatless day, and these were almost religiously observed by practically the whole population as a patriotic duty. So effectively was conservation impressed upon the public mind that a new verb, "to hooverize," came into common use to describe food saving, and was soon used to designate saving in other commodities as well.

The most effective measure for securing national observance with uniform and definite rules for saving was the pledging of housewives, hotel and restaurant keepers, and retail dealers to the voluntary observance of "less" days and other standardized methods of saving. As a result of campaigns for signed pledges, some 14,000,000 families, 7,000 hotels and public eating-places, and 425,000 retail dealers were enrolled in the United States as definitely pledged to the observance of the food conservation programme. Retail dealers in food were eventually required to limit their sale of wheat flour and to require the purchase of a certain specified proportion of substitutes as an accompaniment of every purchase of wheat flour. Wasteful commercial and industrial practices such as faulty loading of railroad cars with perishable foods and the acceptance by bakers of bread returned when stale were prohibited.

In the Lever Act, Congress provided that after Sept. 10 1917, foods, fruits, food materials or feeds should not be used in the production of distilled liquors, and further gave the President power to prohibit the use of these materials in the production of malt or vinous liquors when he should determine a necessity therefor existed. On Dec. 10 1917, the President issued a proclamation limiting the consumption of foodstuffs by brewers in the production of malt liquors to 70% of their consumption in the year 1917. Maltsters and near-beer manufacturers were also licensed and subjected to rules limiting their use of grain. In Sept. 1918, the grain supply outlook called for further restriction on consumption and on Sept. 16 1918, the President issued a proclamation prohibiting the use after Oct. 1 1918, of any food or feed, except malt already manufactured, in the production of malt liquor, including near-beer. This proclamation brought into operation full restrictions against the use of food-stuffs in the production of any distilled or malt liquor. Since these were measures taken for the conservation of food-stuffs only, they did not, however, prohibit the sale of intoxicating beverages, although a "War Time Prohibition Act," passed by Congress Nov. 21 1918, did provide for

war-time prohibition pending demobilization of the army, and beginning on July 1 1919. This, however, was a measure of prohibition for protection of the soldiers and not a food control measure. The use of food in other manufacturing trades was also controlled and restricted by the regulations of the Food Administration, particularly the use of sugar in the manufacture of candy and other non-essential sweets. The conservation programme was in full force from Sept. 1917 until Nov. 1918, when it was withdrawn shortly after the Armistice. The results show that after the United States came into the war, and notwithstanding the exhaustion of its reserves and the decrease of its basic supplies, the volume of food exports to the Allies in these critical months was such that it saved the Allied situation. Without very much more than the usual shipments from the United States the food supply of the Allies would have been reduced below the danger point. In the three years before the war the average food exports were 6,959,055 tons. In the fiscal year 1917–8 the exports were 12,326,914 tons, and, in 1918–9, 18,667,378 tons.

*Stimulation of Production.*—The Department of Agriculture exercised its great influence and used its machinery to reach the farms of the United States with patriotic appeals and advice for the stimulation of production. Response to these appeals, which were disseminated also by the Food Administration, resulted in a considerably increased crop production of 1918. The most important instrument of the Government for stimulating production, however, was the power of the Food Administration to influence prices. This power enabled the Government to guarantee a minimum price to the farmers for wheat, and to assure, though not to guarantee, stabilized prices for hogs, cottonseed products, other vegetable oils, sugar and dairy products. These prices were controlled by the Food Administration through its control of Allied, neutral and Government purchases in the domestic market, supplemented by agreements with the producers of the commodities controlled. In Aug. 1917, a commission composed of representatives of various interests of the population, consumers and producers (though the farmers were given a majority representation), was appointed by President Wilson to determine a fair price for the 1917 crop of wheat. The price agreed upon was $2.20 per bus., which was a 10% increase over the minimum price fixed by Congress in the Lever Act for the 1918 and 1919 crops. This price was then maintained through the Food Administration Grain Corp., which bought at terminal markets any surplus offered at the agreed fair price. The price guaranteed for the 1919 crop was $2.26 per bushel. The effect of these measures was shown in a greatly increased acreage planted in wheat. In 1918 there were 59,181,000 ac. yielding 921,438,000 bus., and in 1919, 73,243,000 ac. yielding 940,987,000 bus., as compared with 52,316,000 and 45,089,000 ac. producing 636,318,000 and 636,655,000 bus., in 1916 and 1917 respectively, when there had been no guarantee. In Nov. 1917 the Food Administration gave an assurance to the farmers of a minimum price for hogs, calculating this price on the basis of the price of corn, the principal hog-feed. Despite the fact that there had been already a decrease of 5,000,000 stock hogs at the beginning of this attempt at stimulation, the number of hogs slaughtered in public markets in the fiscal year 1916–7 was 40,201,018, in 1917–8, 35,543,037, and in 1918–9, 44,398,389. The assurance given in the fall of 1917 did not affect production until the spring of 1918, and showed its effect most clearly in the heavy marketing season in the fall of 1918. Producers of vegetable oils (from cottonseed and peanuts) were assured in Sept. 1918, of 17½ cents per lb. for their crude oil, and this price was maintained for them until July 1 1919. The supply of all vegetable oils in the United States was in 1916, 1,745,574,000 lb., in 1917, 1,742,931,000 lb., and in 1918, 1,911,917,000 lb. It was not possible to secure any great increase in domestic sugar production because of the labour shortage, and special attention was therefore devoted to the stimulation of West Indian production. In Aug. U.S. and Cuban producers were assured of $7.35 per 100 lb. refined, Atlantic seaboard basis; this was increased in Sept. 1918 to $8.49 for Cuban and $8.82 for U.S. sugar, and this price was held until Sept. 1919 by the Sugar Equalization Board. In 1917 the total sugar produced in American and Cuban territory was 5,159,000 tons, in 1918, 5,500,000 tons and in 1919, 6,052,000 tons. These statistics of increased production of wheat, hogs, vegetable oils and sugar show that the producers of the United States responded quite as effectively as did the consumers to the appeals of the Government for war service in the matter of food.

*Price Stabilization.*—Under the highly artificial and unusual conditions of world supply and of concentration of demand upon the U.S. markets there was constant danger of wide and rapid fluctuations in the prices of affected commodities. One of the principal problems of the Government was the prevention, or at least mitigation, of fluctuations of prices for food products in order, first, to safeguard farmers against sudden and disastrous reductions of price such as would discourage production; second, to protect consumers against undue rises which would bring hardship to wage-earners and the industrial population generally, cause strikes and impair war-time efficiency. Again the United States profited by the experience of European Governments and avoided the difficulties which had been found to follow attempts to secure price-stabilization by fixing maximum prices. With the Government's control over the large purchases, and the consequent power to influence the demand and the price at which the dominant buyers bought, it was found possible to secure the desired stability by the commercial operations of purchase and sale and the regulation of distributors without unduly disturbing the normal business methods of the country. The direct control for stabilization purposes was largely confined to breadstuffs (wheat and rye), pork products, beef products, sugar, preserved fruits, and certain dairy products; as it was evident that if the prices of these basic commodities for which there was the greatest demand could be held at a stabilized level, the prices of other commodities connected with them could not fluctuate. For example, if the price of pork products was held stable, the price of corn, which is chiefly consumed by hogs, could not vary from its proper relation to hog prices. Indirect control over the prices of certain products such as wheat, rye, barley, pork products, canned fish and condensed milk, was in the hands of the Government through its control over the foreign buying, because these commodities were exported in such quantities that the power to determine the export price practically determined the price in domestic markets. In the case of sugar, agreements were executed with the Allied Governments which gave a joint commission control of the buying in Cuban and Porto Rican markets, and this arrangement combined with the Government's powers in regard to producers, gave effective control over this commodity. With reference to rice, canned sardines, cottonseed products, dried fruits and city milk, agreements were reached with producers and manufacturers that provided for the maintenance of such stabilized prices as would protect producers and the public. With basic prices thus controlled, the inflation of prices in the hands of the distributors between the producer and consumer was prevented chiefly by fixing for each link in the chain of distribution a maximum margin of profit. This was possible with wholesale distributors because they were licenced by the Food Administration and required to observe its rules and regulations. Retailers of less than $100,000 gross business annually, being exempt from licence, were not subject to regulations, except indirectly through the wholesalers. The most effective method of control devised for the retailers was the publication of a "fair price list" in the local papers of each city and town, stating what was considered a fair maximum price for each of the principal commodities. These prices were determined by Fair Price Boards made up of local business men and women selected by the Food Administration's representatives. Care was taken to keep each local Fair Price Board correctly informed as to basic prices so that the maximum prices fixed for its locality would differ from those elsewhere only in so far as costs were increased or decreased by local conditions. The principal feature of this control and stabilization of prices for food products in the United States as distinguished from that in Europe is that control in the United States was exercised through the ordinary machinery familiar to the trade, that is, through the pressure of sales and other business methods, supplemented to only a slight extent by legal regulations as such. The particular advantage of this policy was that it allowed prices to respond to the real changes in value brought about by the inevitable war-time expansion of currency and credit and the increase of production in other lines, while it prevented rapid fluctuations from local and fleeting causes. The success of this control is apparent from the small rise in food prices during the war period, particularly in comparison with the rise both preceding and succeeding the control period. The chief aim of the control, namely, the protection of both the consuming public and the farmer, was shown to have been successful by the industrial peace and prosperity during the war and the increased production of the farmer.

*Control of Speculation and Profiteering.*—In addition to the measures above described as "price stabilization," the Food Administration had special rules and regulations governing food distributors which were particularly aimed at the prevention of profiteering and speculation under war conditions. Food distribution inevitably is a speculative business. The great supply comes on the market during a comparatively short period of the year, and the function of the distributor is to hold and distribute this supply throughout the year. A part of the distributor's profit must be regarded as an allowance for the speculative risk he necessarily takes in respect to his future market. This, like the other factors of his profit, is ordinarily regulated by competition under the law of supply and demand, but in time of war, when the demand was practically unlimited, the Food Administration had to interpose further checks. The principal measures were the following:—(1) As stated above, maximum margins were established for licenced dealers; that is, a fixed percentage of profit was prescribed which the licensee was forbidden to exceed. The determination of these margins was one of the most difficult problems of the food administrator, particularly because a margin sufficient for the large-scale operator, whose turnover was large and efficiency high, would not provide any profit for the small operator with higher costs. To have driven the small operator out of business would have deranged the competitive system after the war and left the public exposed to the danger of control of food supplies by a few large concerns. (2) The trading in futures on produce exchanges was restricted, and for some commodities (sugar, cottonseed oil, butter, etc.) entirely eliminated. In the case of other commodities like corn, where the trading in future supplies is an indispensable part of the system of distribution, the quantity that could be sold under any one contract to any one firm was limited through the cooperation of the exchanges. The fact that the

Government bought and sold wheat made dealing in futures in that commodity non-essential and it was prohibited absolutely. (3) The period and volume of holdings of food in storage were regulated and without special permit from the Food Administration could not be changed. The prosecution of hoarders under the hoarding provisions of the Lever Act also prevented dealers from holding excessive quantities of food for speculation. (4) Detailed regulations were made in the different trades requiring that all food should pass in straight lines through the chain of distribution. A miller, for example, was allowed only to sell to a wholesaler, a retailer or consumer. A wholesaler could buy only from a miller and sell only to a retailer or consumer. This prevented the addition of unnecessary layers of profit to the price of food passing through too many hands on the road from producer to consumer. (5) The embargo on exports without permit was a very effective discouragement to the speculator. With a controlled market in the United States the speculator's chief hope lay in foreign sales and these were also subject to the inspection of Government agents who would not approve permits for the exporting of obviously speculative shipments. (6) The stabilization of prices, above discussed, was one of the important implements in preventing speculation. The Food Administration was able, for example, to advise the public that during considerable periods flour should be about $12.50 per barrel retail, and sugar about 10 cents per pound. These announcements served, just as did the published decisions of the Fair Price Committees, to restrain through the power of public opinion those who wished to profiteer. (7) Profiteering by licensees of the Food Administration could be punished by withdrawal of the licence to operate the business. The Food Administration maintained an enforcement division which exacted penalties from detected profiteers, but only in a comparatively few cases were licences revoked. For the most part the profiteer was allowed to continue his business after publicly expressing his contrition and paying to some organization such as the Red Cross a fine in excess of his undue profits. Flour-millers were also under agreement to turn over to the Government, by a nominal sale to the Grain Corp., their profits in excess of an agreed amount. Receipts from this source exceeded $6,000,000. Hoarders of food were also subject to criminal prosecution and penalty under a special provision of the Lever Act.

*Control of Exports.*—The first object of this control was to confine American food exports so far as possible to the Allies, forcing neutrals to go to more distant markets for any commodities which they could thus obtain. The second object was to tighten the food blockade against the enemy by preventing direct or indirect leakages. An example of indirect leakage was the large exportation from the United States of feed by neutrals, who thus greatly increased their live stock herds, and then shipped a large part of the resultant animal products into Germany. Since the American and Allied populations were denying themselves severely because of the lack of shipping, it was deemed a just war measure to require the neutrals to do without goods that would benefit the enemy only, if the supplying of those goods required shipping from the United States. The Government maintained representatives in each neutral country in Europe and South America for determination of their production and of the actual necessities of their imports to prevent suffering among their population. It was further necessary to require measures of rationing among neutrals to limit their consumption. While neutrals did not suffer undue privations, subsequent reports from Germany showed that under this pressure the German supply of food from adjoining neutral sources fell from 77,000 million calories per month in 1917 to less than half that amount per month in 1918. Furthermore, the neutrals were required to furnish shipping to the United States as a consideration for their supplies of food and other commodities, and upwards of 1,000,000 tons of neutral shipping was thus transferred to Allied service. The control of exports was removed by the War Trade Board, the governmental agency exercising it, early in 1919, although its removal proved premature as it facilitated speculation which resulted from over-exporting food for commercial purposes.

*Control of Imports.*—The important food commodities imported by the United States before the war were sugar, coffee, vegetable oils, rice and cocoa. The price of these commodities was influenced to a considerable degree, after the United States entered the war, by the elimination of competition between the United States and any of the Allies when purchasing in the same foreign markets. Prices were thus kept at reasonable figures for domestic consumers and the expenditure of excessive sums in foreign markets was prevented. One special concern of the Food Administration, acting as the agency in control of imports, was the retention of ships sufficient in number and size to carry essential imports. Small vessels and sailing ships not capable of transatlantic transport were assigned to the shipping division of the Food Administration, and arrangements were made with committees of the various trades to assign space to their members and to issue import permits, after agreement as to conditions of sale within the United States. The control over imports was thus coördinated with the control over exports so as to harmonise with the general price stabilisation programme of the United States.

*Cost and Accomplishments of Food Control.*—The total of Congressional and Presidential appropriations expended by the Food Administration from beginning to end was $7,862,669. Since the Food Administration was the governmental food control agency, this sum may be taken as the governmental expenditure for food control. The $155,000,000 of capital of the Grain Corp. and the Sugar Equalization Board was handed back to the Government intact, and large profits were earned by each corporation. The neutral countries advanced the charges for their shipping enormously and to protect the United States against this excessive cost, a profit was made on the sales of food to them. The profits of the Grain Corp. and Sugar Board during the period of the Food Administration, in operation at home and abroad, exceeded $60,000,000. The food control may therefore be credited by the Government with a net profit of $50,000,000. But the savings of the people of the United States through the control of prices, through the prevention of discontent and strikes, and through the contribution of food to the Allies, cannot be measured in dollars. The possibility of great achievement under severely trying conditions was again demonstrated because of the spirit of willing sacrifice and coöperation exhibited by the American people. America came through the war with its markets intact and its distributing and producing agencies improved rather than the reverse, so that it was able to supply sufficient food in the months following the Armistice to save practically the whole of Europe. This latter achievement is not a part of the story of food control but it is a very interesting sequel to it. The value of the food commodities furnished to the Allies and the liberated countries from July 1917 to July 1919 amounted to about $3,670,000,000. (W. C. M.)

**FOOTBALL:** *see* SPORTS AND GAMES.

**FORAIN, JEAN LOUIS** (1852– ), French painter and illustrator (*see* 10.628). His cartoons and caricatures during the World War were among the most striking and vigorous in the French press. Afterwards he devoted himself rather to easel painting of a symbolical character.

**FORAKER, JOSEPH BENSON** (1846–1917), American politician (*see* 10.628), died in Cincinnati, May 10 1917. His retirement from the Senate in 1909 followed the publication of certain letters supporting the charge that he had received money from the Standard Oil Company. In 1914 he was again a candidate for the Senate in the Republican primaries, but was defeated by Warren Gamaliel Harding. In 1916 he published *Notes on a Busy Life.*

**FORBES-ROBERTSON, SIR JOHNSTON** (1853– ), English actor (*see* 10.639), was knighted in 1913, and retired from regular work on the stage in the following year.

**FORD, HENRY** (1863– ), American manufacturer, was born on a farm at Greenfield, near Detroit, Mich., July 30 1863. He received only a common-school education in the local school and when about 15 years old went to Detroit, where he learned the machinist's trade. There a little later he began to work for the Edison Illuminating Co., and became interested in the problems of self-propelled vehicles. He worked on the construction of a gasoline engine, making all the parts himself, and in 1892 produced his first motor-car, a very clumsy vehicle, somewhat resembling a tricycle propelled by a one-cylinder engine. He continued his experiments and in 1898 was able to interest a few capitalists in his scheme. He had from the beginning a sincere desire to benefit the people, and was determined to produce a car which could be sold at a price within reach of persons of small means, the profits to come from quantity sales. His plan, however, did not coincide with that of the other members of the early company, and he withdrew. In 1903 he organized and became president of the Ford Motor Co. of Detroit, which ultimately became the largest producer of cars in the world, turning out at a very low price no fewer than 1,000,000 in the single year, 1920, and employing 75,000 men. Parts were standardized and methods devised for quickly assembling the various units that went to make up each car. At the beginning, however, serious difficulties were encountered. As early as 1895 a patent had been secured by George B. Selden, of Rochester, N. Y., which seemed to cover every type of gasoline engine used on a self-propelled vehicle. This supposed "blanket" patent

had led other manufacturers of automobiles to form the Association of Licensed Automobile Manufacturers. They paid for the privilege of using the engine and announced that they would sue any unauthorized producer. Suit was brought against the Ford Motor Co. the very year of its organization, and prospective buyers of the Ford cars were warned that they would be subject to prosecution. The Ford Co. advertised their car widely, declaring that they would give full protection to their customers. At first the suit brought against the Ford Co. was successful, but on appeal it was declared in 1910 that the Selden patent applied to a particular type of engine only, and that the engine manufactured by the Ford Co. did not infringe the patent. In 1909 the Ford Co. erected a factory just outside Detroit, covering 47 acres. As the demand for cars increased, other plants were erected in Canada and England. In 1914 a profit-sharing plan was announced whereby a large percentage of the company's profits would be returned to the workers, and at the same time a minimum wage of five dollars a day was fixed. In 1919 the minimum wage was set at six dollars for approximately 28,000 of the workmen. The company undertook to do much for the welfare of its men, providing a large body of social workers among them, and furnishing legal and medical aid free. A school was founded for giving instruction to foreigners in the English language. This was all undertaken with the idea of securing greater efficiency in the shops. In 1914 Mr. Ford contributed $2,000,000 to a hospital that was building in Detroit, and later added $3,000,000. On the outbreak of the World War he came forward as a pronounced pacifist, and in Sept. 1915 announced that he had set aside $1,000,000 to fight preparedness in the United States and other countries then at peace. In Dec. 1915 he chartered a ship, and with a band of invited pacifists sailed for Europe, hoping to bring about a conference of the belligerents that would result in peace before Christmas. But nowhere was official recognition given the party and dissension arose among themselves. Mr. Ford, after reaching Christiania, returned to America, where he continued to work against preparedness. He assailed the Navy League and the National Security League, alleging that they were supported by munition manufacturers. In Sept. 1916 be brought suit for $1,000,000 against the *Chicago Tribune* for libel, having been called an anarchist in one of its editorials. After three years' litigation he was awarded six cents and the costs of the trial. When America entered the World War he gave full support to the Government and became a member of the Shipping Board, devoting his attention to standardizing production. He placed his efficient plants at the disposal of the Government and some were converted into producers of submarine chasers and small tanks. In 1918 he accepted the Democratic nomination for U.S. senator from Michigan, but his Republican opponent, Truman H. Newberry, was awarded the election. Charges of excessive expenditure and fraud were lodged against Mr. Newberry, who was tried and convicted. On appeal the U.S. Supreme Court reversed the decision. On Jan. 12 1922 the Senate decided, by a vote of 46 to 41, that Newberry was entitled to retain his seat. On Jan. 1 1920 Mr. Ford resigned as president of the Ford Motor Co., being succeeded by his son, to devote himself to developing the farm tractor business. Shortly before, he had purchased the *Dearborn* (Mich.) *Independent*.

**FOREL, FRANÇOIS ALPHONSE** (1841–1912), Swiss geographer, was born at Morges on Lake Geneva Feb. 2 1841. He was trained for and practised in the medical profession, but his life-interest was found in the lake on whose shore he lived, and, from that, in limnology, the science of lakes. The study of Lake Geneva in all its associations led him to that of geology, physics, biology, and anthropology, and he set forth the results of his researches in the three stately volumes of *Le Léman* (1892–1902). On the science of limnology more generally his standard work is *Handbuch der Seenkunde* (1901); in this connexion his investigations of the previously mysterious movements of lake-waters known as seiches call for special notice. Among other researches of Forel's, those in seismology and upon Swiss Alpine glaciers are noteworthy. He died at Morges Aug. 7 1912.

**FORESTRY** (*see* 10.645).—The period 1918–21 was dominated by the abnormal conditions produced by the World War of 1914–9, which demonstrated, as only such a gigantic upheaval could have demonstrated, the vital importance of timber in time of war and the necessity for maintaining adequate and readily accessible supplies of this commodity.

(1) BRITISH EMPIRE.—The war found Great Britain, accustomed to rely mainly on imports from abroad, without any efficient organization for the supply of home-grown timber. The development of the submarine campaign, the growing scarcity of shipping, and the necessity for employing the available shipping as little as possible for the conveyance of such a bulky article as timber, served to focus attention on the question of ensuring supplies of home-grown timber in the event of another great war. The whole question was examined in detail by a forestry sub-committee of the Reconstruction Committee, appointed in 1916, the terms of reference being:—"To consider and report upon the best means of conserving and developing the woodland and forestry resources of the United Kingdom, having regard to the experience gained during the war." The final report of this sub-committee (Cd. 8881, 1918) drew attention to the risk involved if future home-grown supplies are not safeguarded, and proposed a scheme calculated to render the United Kingdom independent of imported timber for three years in an emergency. This scheme, while making due allowance for an improved yield from existing woods, recommended the afforestation in 80 years of 1,770,000 ac. of unplanted land, of which two-thirds should be planted in the first 40 years. The cost of the scheme was estimated at £3,425,000 during the first 10 years, with a possible total expenditure of £15,000,000 during the first 40 years, after which it was reckoned that the scheme should be self-supporting. Apart from the question of financial returns, however, the sub-committee justified its proposals on the ground that forests are a national necessity and that the interests of national safety demand that more timber should be grown in the British Isles. With the view of carrying this scheme into effect it was proposed to constitute "a forest authority equipped with funds and powers to survey, purchase, lease and plant land and generally to administer the areas acquired, with compulsory powers to be exercised, after due enquiry and the award of fair compensation."

The recommendations of the sub-committee resulted in the passing on Aug. 13 1919 of the Forestry Act (9 and 10 Geo. 5, ch. 58) and the constitution of a forestry commission consisting of three paid and five unpaid members equipped with wide powers for the promotion of afforestation, the production and supply of timber, the purchase or lease of land suitable for afforestation, the purchase or sale of standing timber, the establishment of woodland industries, the promotion of forestry education, experiment and research, and the destruction of pests and vermin. This marks the most important step yet taken in regard to British State forestry; as a result a definite programme of land acquisition and planting has been framed and is being carried out, a forest service has sprung into being, and the outlook of State forestry in the United Kingdom is clearer than it has ever been in the past. Not the least of the benefits conferred by an extensive scheme of afforestation will be the encouragement of small holdings by providing employment in the form of forest work at a time of the year when agricultural work is suspended.

*The Imperial Outlook*.—The year 1920 marked an important step in the progress of forestry in the British Empire, in that for the first time a forestry conference representative of the various parts of the Empire assembled in London at the invitation of the British Forestry Commission. The deliberations of this conference tended to confirm the view that, generally speaking, the Empire is dissipating its vast natural forest resources, and that if the conservation and regeneration of the forests are to be carried out effectively, each Government of the Empire should lay down a definite forest policy to be administered by a properly constituted and adequate forest service. The conference emphasized the necessity for a systematic survey of the forest resources of the different parts of the Empire, with a view to the collection and dissemination of facts as to the state of the forests and the de-

mands on them; and in order to effect this object it recommended the establishment of an Imperial Forestry Bureau, incorporated by Royal Charter, somewhat on the lines of the Imperial Mineral Resources Bureau. This bureau, to be supported mainly by funds provided by the Governments of the Empire, would have for its chief objects the collection and dissemination of information on matters connected with forestry and forest resources, and the coördination of work done by existing agencies.

The recommendations of the conference have not yet had time to take full effect, but its first fruits were in evidence in the early part of 1921, when in the first place the preliminary steps towards the establishment of an Empire Forestry Association were completed, and in the second place the important question of the future training of forest officers formed the subject of recommendations by a committee specially appointed to enquire into the matter. The newly constituted Empire Forestry Association is an unofficial organization, not directly connected with the proposed Forestry Bureau; its chief objects are to serve as a link between the associations already existing in the United Kingdom and other parts of the Empire, and between individuals engaged in forestry work, to foster public interest in forestry throughout the Empire, to ensure general recognition of the importance of forest management, to collect and circulate information as to existing forest conditions and the future timber requirements of the Empire, to provide a clearing-house of information and a centre for coöperation, and to organize meetings for the discussion of the problems connected with the growth and utilization of timber. Among other functions of the Forestry Association will be the publication of a quarterly journal.

The question of the future higher training of forest officers for those parts of the Empire having no place of higher training of their own was discussed at some length by the British Empire Forestry Conference, which recommended that the training should be carried out at one central institution, and that a complete university education should be regarded as a necessary preliminary to this training. An interdepartmental committee on imperial forestry education, appointed to prepare a scheme for giving effect to the resolutions of the conference, recommended that the work already being done by universities in maintaining courses of training in forestry should not be interfered with, but that efforts should be made to coördinate all these courses, to bring them up to a common level, and to utilize them as a preliminary to a higher course of training at one central institution. It was proposed that this institution should be located at Oxford, incorporated with the university, and governed by a board appointed one-half by the university and the other half by the departments or Governments concerned, who should jointly guarantee to the board an annual sum sufficient to pay the costs of the institution. It was further proposed that the institution should be responsible not only for the higher training of new recruits for the various forest services, but also for the provision of special or revision courses for officers already serving, and that it should become a centre for research in silviculture, forest entomology, pathology, soil science, and matters affecting forest production generally. These proposals, if carried out intelligently, should be of far-reaching importance in so far as the future personnel of the forest services of the Empire is concerned, for it has been recognized for some time and the matter was emphasized during the discussions of the British Empire Forestry Conference, that the methods of recruitment and training in force hitherto have left much to be desired, and that a great improvement in the standard of forestry education is required.

Great as has been the progress in the past in some parts of the Empire, in other important parts scientific forestry may be said to be as yet in its infancy, and the importance of forest conservation and systematic management is as yet imperfectly realized. Nevertheless, if legislation can be accepted as an indication of the desire to remedy matters, there are signs of a better appreciation of the duties of the State towards forestry during recent years, for since 1906 and during the war numerous forest enactments have been passed in different parts of the Empire.

*India* had introduced forest legislation long before this period, in the shape of the Indian Forest Act (VII. of 1878) which with certain amendments is the basis of forest policy of the present day. Under this Act State forest for waste land may be set aside as reserved or protected forest; the Act also provides for the constitution of village forests, the protection of forests and trees, the control of forest produce in transit, and other matters. Other special enactments in the Indian Empire are the Burma Forest Act (IV. of 1902), the Madras Forest Act (V. of 1882), and certain forest regulations applying to other provinces.

Forest legislation in the *Malay States* in the form of the Straits Settlement Ordinance (No. XXII. of 1908) is founded on Indian practice, and follows the Burma Forest Act. In the Federated Malay States a Federal enactment, following the Indian model, was passed in 1914 and revised in 1918 as Enactment No. XXXIV. of 1918; the Unfederated States have separate enactments.

In *Canada* the Forest Reserves and Parks Act, passed by the Dominion Parliament in 1906, with subsequent amendments, authorizes the setting apart of forest reserves and Dominion parks. The British Columbia Forest Act of 1912, with subsequent amendments, places the forests under the charge of the Forest Branch. The Forest Fires Prevention Act of Ontario, passed in 1917, provides for the protection of forests from fire and for the appointment of a provincial forester. The Nova Scotia Forest Protection Act of 1913 and the New Brunswick Forest Act of 1918 provide for fire protection, and the latter establishes a forest service. Quebec has forest legislation dealing with fire protection and other matters.

In *Australia* forest legislation appears in various forms. The Forest Act of South Australia, which dates from 1882, places the control of forests in the hands of a commissioner with considerable powers. The Queensland State Forests and National Parks Act, 1906, provides for the setting aside of State forests and national parks, and the Land Act of 1910 deals with timber rights and sales. In Victoria forest legislation is represented by the Forest Act of 1907, as consolidated and amended in 1915, and the Forest Act of 1918, which places the forests under a commission of three with wide powers. The New South Wales Forestry Act of 1916, which consolidated forest legislation, provides for the constitution of State forests and their control by a commission of three. In New Zealand a State Forest Act was passed in 1908, but as it proved defective in certain respects it was amended by Section 34 of the War Legislation and Statute Law Amendment Act of 1918.

In *South Africa* the Union Forest Act of 1913, amended in 1917, consolidates the laws of the four provinces of the Union and deals with the tenure, demarcation, regulation and protection of forests. In *Southern Rhodesia* the Cape Colony Forest and Herbage Act of 1859 and the ordinances of the Rhodesian Legislative Council provide for forest protection. In *British East Africa* (Kenya Colony) the Forest ordinances of 1911, 1915 and 1916 give wide powers for constituting reserved forests, and provide for a forest service and other matters. In *Nyasaland* the Forest ordinance of 1911 and the Crown Lands ordinance of 1912 prohibit the cutting of certain kinds of timber. In *Nigeria* the Forest ordinance of 1916 gives the governor wide powers in forest matters.

This brief sketch of legislative action taken, particularly in recent years, indicates the awakening interest in the natural forest resources of many parts of the Empire. There was still in 1921, however, much to be done before future progress could be assured. One of the most pressing needs is the building up of adequate and efficient services of trained forest officers where these do not exist; in this way the forests will be brought by degrees under scientific management, and the wasteful methods of felling and conversion which have so often been a feature of forest exploitation in the past, and the destruction of extensive areas of valuable coniferous forests, will be kept in check. Apart from direct State action, however, much good should result from measures which will influence public opinion towards an appreciation of the value, utility, and national importance of forests, and the necessity for safeguarding their future by conservation, protection, and efficient management.

*War Supplies.*—During the war the timber resources of Great Britain itself were taxed to their utmost. For some years prior to 1914 the annual imports of manufactured timber averaged about 10,000,000 loads. The imports diminished in 1914 to 8,433,000 loads, in 1915 to 7,666,000 loads, in 1916 to 6,319,000 loads, and in 1917 to 2,875,000 loads. At the outbreak of war there were considerable stocks of imported timber which, together with imports, mainly from northern Europe, sufficed to meet all urgent military demands during the first year of the war. In the latter part of 1915, however, owing largely to the advent of the submarine campaign, it was found necessary to take steps towards an increase in the supply of converted timber, although even prior to this, anxiety had been felt as to the maintenance of the supply of pit props for the mines. It was at this time, therefore, with the appointment of a Home-Grown Timber Committee under the Board of Agriculture, that the first serious steps were taken towards utilizing home-grown timbers to the utmost, while at the same time ensuring the greatest possible economy in the use of timber. Early in 1917 the tonnage stringency and the necessity for curtailing imports called for stricter control; this control was assumed by the War Office, who took over the staff of the Home-Grown Timber Committee and formed a Timber Supplies Department under a Director of Timber Supplies. This department was handed over soon afterwards to the Board of Trade. The exploitation of the home timber resources was carried out not only

by British labour, but also to a large extent by the Canadian Forestry Corps and other units. Canadian sawmilling plants were erected in many parts of the country, and the production of sawn timber went on to the extent of depleting many well-wooded districts, the reforestation of which will present an urgent problem for some time to come.

During the war the British army played an important part in the exploitation of the French forests, and here again the Canadian Forestry Corps, which at the close of hostilities numbered some 17,000 men, did signal service in providing the requisite supplies of timber for military purposes.

The eastern theatres of the war were supplied largely from India. Figures available refer only to the period from April 1917 to Oct. 1918, during which timber supplies were in the hands of the Indian Munitions Board. The total quantity of timber shipped during this period to overseas destinations, namely, to Mesopotamia, Egypt, Salonika, Aden, East Africa, the Persian Gulf and elsewhere, amounted to 198,000 tons, while in addition 30,000 tons were utilized for war purposes in India, making a total of 228,000 tons, or an average of 12,600 tons a month. In addition railway sleepers were supplied for over 1,800 m. of track. The bulk of the work connected with the exploitation of the forests for the supply of this timber was done by the Indian Forest Department.

all events, must be regarded as largely abnormal. The balance is + or − according as the total exports are greater or less than the total imports.

It will be seen that the chief importing country of the British Empire is the United Kingdom and the chief exporting country is Canada. During the period 1909–13, however, the United Kingdom drew 88% by volume and 83% by value of her imports from without the Empire, the chief sources being Russia, Scandinavia, S.W. Europe (for pitwood) and the United States. Of the Indian exports teak represents about 85%, while imports consist mainly of jarrah timber and railway sleepers from Australia and deal and pine timber. Of a total of 7,133,800 loads exported by Canada, 1,058,000 loads valued at £3,525,000 were imported by the United Kingdom. S. Africa imported 10,452,000 cub. ft. of unmanufactured timber from Scandinavia, 2,632,200 cub. ft. from the United States, 440,500 cub. ft. from Australia, and 92,900 cub. ft. (teak) from India; imports of manufactured timber were chiefly from Scandinavia. As regards the Australian states, about half of the W. Australia imports were from the United States and rather more than one-sixth were from Scandinavia, while of the exports, about one-third went to the Eastern states and the remainder to India, the United Kingdom, New Zealand and S. Africa in the order named; imports into Victoria consisted mainly of soft-woods from Scandinavia, the United States, Canada and New Zealand; Queensland imports were principally from overseas and exports were to other States of the Commonwealth; New South Wales exports were chiefly to New Zealand, the Pacific Is. and the East. (R. S. T.*)

(2) UNITED STATES.—At the beginning of 1921 the United States was facing the certainty of a future shortage of timber.

TABLE I.—*Area of British Empire Forests.*
Square miles (rounded off to nearest ten).

| Country | Agricultural Land | Forest | | | Other Land | Total Land Area |
|---|---|---|---|---|---|---|
| | | Merchantable | Unprofitable or Inaccessible | Total | | |
| United Kingdom | 97,080 | 3,860 | 1,320 | 5,180 | 17,210 | 119,470 |

| Total | | | | 1,857,520 | | 9,195,700 |

*Omitted in total.

*Imperial Statistics.*—A complete survey of the forest resources of the British Empire was in 1921 still far from being an accomplished fact, and in many cases area statements must for the present be accepted as only roughly approximate. Subject to this limitation the accompanying tables, compiled from information furnished by the different Governments concerned to the British Empire Forestry Conference in 1920, give the latest statistics available. Of the two area statements, Table I. gives the estimated area of forest, agricultural land and other land in each country, and Table II. gives a classification of the forest area according to ownership. Certain parts of the Empire, for which statistics are not available, have been omitted.

Table III. shows the quantities and values of exports and imports. As the figures refer partly to pre-war periods and partly to the period of the war they are not fairly comparable, and in the latter case, at

Yet a continuous supply is absolutely indispensable for the prosperity of the nation. The dangerous condition of forest depletion has already been reached. The U.S. Forest Service, in a report on *Timber Depletion, Lumber Prices, Lumber Exports, and Concentration of Timber Ownership*, submitted to the Senate June 1 1920, sets forth that of the original 822,000,000 ac. of virgin forest only 463,000,000 ac., little more than half, are left. Of this but 137,000,000 ac. are virgin timber. There is some second growth of saw-timber size on 112,000,000 ac.; 133,000,000 ac. have second growth under saw-timber size; and 81,000,000 ac. (as much as the combined forest areas of Germany, Denmark, Holland, Belgium, France, Switzerland, Spain and Portugal)

*The United Kingdom exports include 87,500 loads which are re-exports, valued at £795,200.

have been cut, burnt and neglected until they produce practically nothing. The United States is cutting what timber remains more than four times faster than it is being reproduced. In addition to the actual timber shortage, the forests remaining are so far from the wood-using industries that the distance to markets often makes the shipping of needed supplies either unduly costly and uncertain or altogether impracticable.

Of the 48 states, 30 produce less wood than they use. These include by far the larger part of the agriculture, industries, wealth and population of the nation. They are Vermont, New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Delaware, Maryland, Georgia, Ohio, Indiana, Illinois, Kentucky, Missouri, Michigan, Wisconsin, Minnesota, Nebraska, Kansas, Oklahoma, Colorado, Iowa, North Dakota, South Dakota, Nevada, New Mexico, Utah and Wyoming.

The merchantable timber remaining in the United States is estimated at 2,215,000,000,000 board-feet. About one-half of it is in Washington, Oregon and California, and over 60% W. of the great plains. Concentration of ownership has kept pace with forest destruction; and half the privately owned timber in the United States is held by 250 owners. The depletion of resources is not limited to saw-timber. Since 1909 the country has ceased to be self-supporting in newsprint and other paper, and in 1919 the production of naval stores had fallen off 50% from that of 1899, the first year of satisfactory statistics. Shortages in other forest products are developing also. Since wood is the most generally useful of all materials, and since the shortage and high price of wood affect all industries and all people, its supply has become one of the country's chief economic problems. The 137,000,000 ac. of remaining virgin forest is being cut at the rate of 5,500,000 ac. a year, and at that rate will be exhausted in 25 years. The 81,000,000 ac. of devastated, unproductive forest land is being added to at the rate of 3,000,000 ac. annually. Since three-fourths of the standing timber is virgin timber and since four-fifths of the forest supplies are in private hands, the first and most necessary step is to stop the devastation of privately held timber lands. The next most necessary step—and both are indispensable—is the stopping of forest fires. A careful study of the kinds and quantities of forest products available throughout the world leads to the conclusion that little relief from timber shortage can be found in the importation of forest products from other lands. Because the United States must have wood, and because it cannot be secured abroad, it must be grown at home.

*Government Action.*—The largest and most effective organization engaged in providing future supplies of timber is the U.S. Forest Service. Most of its personnel is employed in caring for the national forests, which in 1920 included 156,632,053 ac., as against 153,933,700 ac. a year before. Roughly, they contain one-fifth of the actual timber land in the United States. There are 152 national forests, of an average area of 1,000,000 ac., each in charge of a forest supervisor. The annual gross receipts in money to the Government from them are almost $5,000,000.

AREA AND STAND BY REGIONS

| REGIONS | TOTAL FOREST AREA (MILLION ACRES) | STAND OF SAW TIMBER (BILLION BD. FT.) |
|---|---|---|
| I - NEW ENGLAND | 54.7 | 49.8 |
| II - MIDDLE ATLANTIC | 58.7 | 44.9 |
| III - LAKE | 57.1 | 110.1 |
| IV - CENTRAL | 58.7 | 144.1 |
| V - SOUTH ATLANTIC AND EAST GULF | 99.0 | 221.7 |
| VI - LOWER MISSISSIPPI | 78.9 | 280.2 |
| VII - ROCKY MOUNTAIN | 60.8 | 258.1 |
| VIII - PACIFIC COAST | 57.6 | 1141.0 |
| TOTAL | 468.5 | 2814.9 |

During the year ending June 30 1920, 597,563 ac. of forest land were cruised, 6,719 ac. planted, 13,222 timber sales involving 1,294,233,000 board-feet of timber made, and 31,301 grazing permits issued for 2,035,432 head of cattle and 7,280,584 sheep, in addition to other live stock. The receipts and expenditures for the national forests during 1910–20 were:—

| | Receipts | Expenditures |
|---|---|---|
| 1910 | $2,041,181.22 | $2,791,275.62 |
| 1911 | 1,968,993.42 | 3,395,730.77 |
| 1912 | 2,109,256.91 | 3,433,285.36 |
| 1913 | 2,391,920.85 | 3,396,762.44 |
| 1914 | 2,437,710.21 | 3,337,648.83 |
| 1915 | 2,481,469.35 | 3,261,455.16 |
| 1916 | 2,823,540.71 | 3,427,110.43 |
| 1917 | 3,457,028.41 | 3,869,362.60 |
| 1918 | 3,574,930.07 | 4,264,367.00 |
| 1919 | 4,358,414.86 | 4,886,747.00 |
| 1920 | 4,798,482.28 | 4,534,000.00 |

It is interesting to note that in 1919 and 1920 the national forests were self-supporting. They are well handled and efficiently protected, and their management has gradually won for them the enthu-

tastic support of western people, many of whom had been hostile to the service and its policies. Permanent improvements in the national forests are estimated to have a value of almost $13,000,000. They include 5,043 m. of roads, 29,419 m. of trails, and 25,031 m. of telephone lines. A substantially complete land classification of the national forests has been made. By the Weeks law, enacted March 1 1911, 1,796,788 ac. of forest in the southern Appalachian and White mountains of the eastern United States have been added by purchase to the national forests. The investment is a good one, since the present value of the land and timber sold is notably more than the original price plus the cost of care and protection. The average price paid per acre was $5.24. The purchased land is distributed in the following States:—

| States | Acres |
|---|---|
| Alabama | 62,966 |
| Arkansas | 36,529 |
| Georgia | 153,665 |
| Maine | 32,153 |
| New Hampshire | 401,026 |
| North Carolina | 326,786 |
| South Carolina | 18,612 |
| Tennessee | 246,675 |
| Virginia | 387,888 |
| West Virginia | 130,488 |
| Total (as of June 30 1920) | 1,796,788 |

It is expected that in the end not less than 7,000,000 ac. will have been acquired under the Weeks law. In addition to the purchase of forest land by the Government, the Weeks law authorized the co-operation of one state with another or with the United States in the protection of forests from fire. An amount ranging from $100,000 to $200,000 has been appropriated by Congress yearly for coöperation under this system, which contemplates that the state shall expend an amount at least equal to that expended by the Federal Government. Twenty-four states have taken advantage of it and the results are excellent.

*Forest Products.*—The Forests Products Laboratory at Madison, Wis., maintained by the U.S. Forest Service in coöperation with the university of Wisconsin, was established in 1911. It studies forest products and the best methods for their utilization. The total of its expenditures to Jan. 1921 is about $2,000,000, and a conservative estimate of the value of its work to American industries is not less than $30,000,000. During the World War about two-thirds of the force of the laboratory was occupied with problems related to war work. Among them were the mechanical and physical properties of different species of woods, methods of seasoning, substitutes for spruce in the construction of aeroplanes, and the strength of laminated structures for plywood. More recently, box testing has resulted in important savings in the manufacture of boxes and has greatly reduced the damage to boxed commodities. The laboratory has made a total of 500,000 tests on the mechanical properties of wood. A study of the influence of decayed wood on the quantity and quality of wood-pulp showed that the loss in stored pulp was probably not less than $5,000,000 a year, much of which could be prevented. This service now has four experiment stations, mainly in the West.

During 1910–20, state departments of forestry increased in number and extended the scope of their work. Thirty-four states now recognize forestry in this way, but the work of their departments is still weak and far below the standard of the Federal service. The area of forest land and the number of forests owned by the states are shown in the following table:—

| State | Number of State Forests | Area (Acres) |
|---|---|---|
| Connecticut | 5 | 3,702 |
| Indiana | 1 | 2,000 |
| Maryland | 5 | 3,500 |
| Massachusetts | 5 | 13,000 |
| Michigan | 82 | 289,515 |
| Minnesota | 4 | 333,000 |
| New Hampshire | 43 | 11,002 |
| New Jersey | 7 | 16,590 |
| New York | 2 | 1,838,322 |
| North Carolina | 1 | 340 |
| Ohio | 2 | 1,720 |
| Pennsylvania | 26 | 1,108,476 |
| South Dakota | 2 | 80,000 |
| Vermont | 13 | 20,135 |
| Wisconsin | 1 | 380,443 |
| Total ac. | | 4,101,745 |

Much encouragement has been given by state departments to private planters of forest trees. Pennsylvania distributes annually about 3,000,000 forest-tree seedlings and "transplants" to private owners who pay only the cost of packing and shipping. The state contemplates an increase of this number to 20,000,000 and the raising of the trees at state-maintained charitable and correctional institutions. New York in 1919 distributed 2,225,000 seedlings at the cost of production. Most of the states supply technical advice to owners of woodland. In many of the states private forest fire protective organizations are common and usually efficient. In the West their work is confined mainly to the protection of valuable standing timber. Elsewhere it covers large areas of second growth or devastated land.

Wood is an essential munition of war and is required in enormous quantities by armies in the field. The U.S. army alone used 450,000,000 board-feet of timber and 560,000 cords of firewood during the war. The 20th Engineers, with a personnel of 18,000 men, operated 81 saw-mills in France and cut approximately 2,000,000 board-feet of timber, ties, piles and poles, in addition to enormous quantities of firewood, every working day. This regiment, composed mainly of lumbermen, was officered largely by trained foresters. Within one year after its formation 90% of the recruited men had landed in France, had built their own railway connexions, and had cut 300,000,000 board-feet of timber and railroad ties, 38,000 piles, and 2,878,000 poles and entanglement stakes. At least 75% of the wood used by the A.E.F. came from the forests of France.

During the decade 1910–20 technical instruction in forestry was crystallized and advanced, and popular instruction and practical demonstration in forestry has taken on a notable extension. Forestry is now widely taught in the agricultural colleges, vocational schools, and in the biological courses of colleges, normal schools, and public schools. Most of the forest schools which give technical instruction were established between 1900 and 1910. There are now 20 technical forest schools in America, a number entirely adequate to meet present demands. The Yale school of forestry and the department of forestry at Harvard grant the degree of Master of Forestry. Most of the other forestry schools give undergraduate courses leading to the degree of Bachelor of Science in forestry or Bachelor of Forestry. Some of the best known are those at the university of Maine, Cornell and Syracuse universities in New York, the Pennsylvania State Forest Academy, and the universities of Michigan, Minnesota, Montana, Idaho, Washington and California.

BIBLIOGRAPHY.—In addition to the authorities cited in 10.660 are: Fernow, *The Care of Trees* (1910); Van Hise, *The Conservation of Natural Resources* (1910); Bowman, *Forest Physiography* (1911); Graves, *Principles of Handling Woodlands* (1911); Schenck, *Forest Utilization* (1911); Elliott, *The Important Timber Trees of the United States* (1912); Fernow, *History of Forestry* (1912); Record, *Economic Woods of the United States* (1912); Recknagel, *Theory and Practice of Working Plan* (1912); Barnes, *Western Grazing Grounds and Forest Rangers* (1913); Bryant, *Logging* (1913); Kellogg, *Lumber and its Uses* (1914); Moon and Brown, *Elements of Forestry* (1914); Record, *Mechanical Properties of Woods* (1914); Roth, *Forest Regulations* (1914); Hawley and Hawes, *Forestry in New England* (1915); Chapman, *Forest Finance* (1916); Ferguson, *Farm Forestry* (1916); Roth, *Forest Valuation* (1916); Toumey, *Seeding and Planting* (1916); Weiss, *Preservation of Structural Timber* (1916); Jeffry, *Anatomy of Woody Plants* (1917); Kinney, *The Essentials of American Timber Law* (1917); Pinchot, *The Training of a Forester* (1917); Snow, *Wood and Other Organic Structural Material* (1917); Taylor, *Hand Book for Rangers and Woodsmen* (1917); Woolsey, *French Forests and Forestry* (1917); Boerker, *Our National Forests* (1918); Betts, *Timber, Its Strength, Seasoning and Grading* (1919); Recknagel-Bentley, *Forest Management* (1919); Brown, *Forest Products* (1919); Ise, *The United States Forest Policy* (1920); Woolsey, *Studies in French Forestry* (1920).) (G. P.)

**FORMAN, HARRY BUXTON** (1842–1917), British man of letters and civil servant, was born in London July 11 1842. He was educated at Teignmouth, and at the age of eighteen entered the postal service, where he remained until his retirement in 1907, being successively controller of the packet service and second secretary. He was for many years associated with the foreign branch of the service. It is, however, as a man of letters, and particularly as an authority on Shelley and Keats, that he is best known (*see* 24.832). His first book, *Our Living Poets*, was published in 1871, and was followed in 1876 by the first volume of his edition of the *Prose and Poetical Works of Shelley*, and in 1886 by the *Shelley Library*. He also published editions of *Keats* from 1883 onwards, and in 1896 *Elizabeth Barrett Browning and her Scarce Books*. His last publication, *Books of William Morris*, appeared in 1897, in which year he was made C.B. He died at St. John's Wood, London, June 15 1917.

**FORMOSA** (TAIWAN).—The island of Taiwan (Formosa), which was ceded to Japan by China in 1895 (*see* 10.669), has an area of 13,839 sq. m., and in 1920 the pop. was 3,654,398, representing a density per sq. m. of 264 inhabitants. The chief towns are Taihoku, Tainan, Kagi and Taichu.

*Administration and Finance.*—Taiwan was placed under a civil administration in April 1896, and legislative steps were taken in the

following year to put the finances of the island on an independent footing. Meanwhile a grant was made from the National Treasury, varying from £710,847 in 1897 to £71,699 in 1906, when the subvention was withdrawn owing to the satisfactory financial condition of the island. The 1920–1 budget balanced with an estimated revenue and expenditure of 94,451,263 yen.

*Government Monopolies.*—The Government monopoly undertakings of the island are opium, salt, camphor and tobacco, the importation of opium and the manufacture and smoking of the drug being strictly prohibited since 1896, except by licence in the case of confirmed smokers. The efforts made by the Government to educate the people with regard to the evil effects of opium-smoking were so successful that the number of licensed smokers had decreased from 117,000 in 1900 to 52,000 in 1919.

In May 1899 the Government took steps to improve the quality and increase the quantity of salt produced, which had hitherto suffered from the fluctuations due to irregular and sporadic private enterprise. There are now some 4,000 ac. of salt fields and sufficient salt is produced to satisfy local requirements and also for export to Japan, Chosen, Karafuto, etc. In 1899 the production of camphor was also controlled and in 1905 the monopoly system was extended to Taiwan-cut tobacco, in both cases with beneficial results.

*Trade.*—The chief commodities exported from Taiwan are tea, rice, sugar, camphor, turmeric, flax, hemp, jute and coal. In 1897 the volume of trade with Japan and overseas trade was 31,230,000 yen; in 1907 it was 58,340,000 yen; in 1910 108,880,000 yen (largely owing to the development of the sugar industry) and in 1912 125,520,000 yen. The World War seriously affected the results in the next few years, but in 1919 the figure of 332,520,000 yen was achieved. Exports to Japan and Korea were 142,200,000 yen and to other countries 35,620,000 yen, the total imports being valued at 154,700,000 yen. The balance of trade in favour of exports was thus 23,120,000 yen, chiefly due to the increased output and higher value of coal and to the good condition of the sugar market.

*Agriculture and Industry.*—Almost the whole of Taiwan is a rice-growing country, yielding two crops a year. In 1919 the rice crops amounted to 24,419,275 bus., an increase of 18 % on the crop of 1909. The oolong and souchong teas, produced in the north of the island, are important exports to foreign countries; the value of the oolong exported abroad in 1919 was 5,346,327 yen, a falling-off against 1918, probably owing to heavy stocks in the American market.

The sugar industry enjoyed great prosperity in 1916 and 1917, the value of the exports being 11,317,643 yen and 15,775,205 yen, respectively. There are some 37 modern sugar refineries in the island with a capacity of 29,200 tons, about 25 less well equipped with 2,550 tons capacity, as well as about 250 out-of-date establishments.

With regard to mineral products, the northern part of the island is again the more productive, as gold, alluvial gold, silver, copper, coal, petroleum and sulphur are all found there. The total value of mineral products in 1919 was 11,167,426 yen; the gold produced being 20,740 oz. (or 22,374 oz. including alluvial gold), valued altogether at 910,311 yen. The coal production was 1,086,907 metric tons (value 8,825,002 yen), the copper 877 metric tons (value 713,221 yen), silver, 20,185 oz. (value 41,459 yen), and sulphur 1,441 metric tons (value 85,791 yen). The value of petroleum was small; and though the oil fields are widely distributed over the island, most of them remain practically unexploited.

The fishing industry of Taiwan owes much of its present prosperity to Government encouragement, although owing to the favourable ocean currents, fishing can be carried out all round the island. Artificial rearing of oysters, prawns, carp, etc., is carried out both in salt and brackish waters, and it is a characteristic of the Formosan fisheries that whilst the natural produce is valued at about 4,000,000 yen, the value of the products of fish culture is 2,000,000 yen.

*Communications.*—The first postal service was opened in April 1895, when, prior to the restoration of peace between Japan and China, the Japanese army occupied Hokoto and established a field post-office. In 1896 postal service for the general public was commenced under the control of the Minister of Communications. In Oct. 1900 the Postal and Telegraph Laws, which had been put into force in Japan proper, were brought into operation in Taiwan by Imperial Ordinances and in the same year the telephone service was first opened between Taihoku and Tainan.

A great increase in the business of the post-office savings bank took place during 1910–20, the number of depositors having risen from 90,893 in 1909–10 to 358,204 in 1918–9, the deposits increasing from 1,900,700 yen to 5,518,178 yen in the same period.

In 1899 the Government commenced planning out a trunk line from north to south of the island, connecting the ports of Keelung and Taku and passing through Taihoku, Taichu and Tainan. Branch lines, further opening up the rice, sugar, tea and mining districts, were gradually completed, so that at the end of the financial year 1918–9 there were 346 m. of railway open to traffic.

In the same year over 9,000,000 passengers and more than 2,000,000 tons of goods were carried, the receipts being 8,013,559 yen.

In addition to the state railways, there were at the end of 1918 over 1,000 m. of railway belonging principally to sugar factories and about 600 m. of track for hand-propelled cars, an important means of local transport peculiar to the island. (H. SA.)

**FORREST, JOHN FORREST,** 1st Baron (1847–1918), Australian statesman (*see* 10.672), was acting Premier of Australia in 1907 during the absence of Mr. Deakin in London, took office again as Treasurer in Mr. Hughes's "National" Cabinet of 1917 but resigned owing to ill-health early in 1918, when he was raised to the peerage, the first Australian to be so honoured. He died, however, at sea on his way to England to take his seat in the House of Lords, Aug. 3 1918.

**FORSYTH, PETER TAYLOR** (1848–1921), British Nonconformist divine (*see* 10.677), died in London Nov. 11 1921. Among his recent works were *The Person and Place of Christ* (Congregational lecture, 1909); *The Principle of Authority* (1913) and *This Life and the Next* (1918).

**FORTIFICATION:** *see* SIEGE WARFARE.

**FORTIS, ALESSANDRO** (1841–1909), Italian statesman, was born in 1841. He joined Garibaldi in 1866 as a volunteer and fought under him in the Trentino, in 1867 at Mentana and in 1870 in France. Under the influence of Aurelio Saffi he became a Republican, and was arrested as a Mazzinian conspirator in 1874. In 1876 he abandoned the Republican party, although still adhering to Democratic ideals. Elected deputy for his native town of Forli in 1880, he helped the royal visit to Romagna, hitherto regarded as a hot-bed of anti-monarchical views. He made a reputation as a parliamentary debater, but lost favour with his constituents who were largely Republican, and only held his seat with the help of Livio Quartaroli, mayor of Forli, and Saffi; when they died his position became untenable and he was not reelected. He then won a seat at Poggio Mirteto, which he continued to represent until his death. He became Minister of Agriculture in the Pelloux Cabinet (1898–9), and in 1905, on the fall of the Giolitti Cabinet, became premier. But his administration fell after seven months over the commercial treaty with Spain, which aroused the violent opposition of the Italian vine-growers. He reconstructed the Ministry, but was beaten at once and had to resign, Jan. 30 1906. He died Dec. 4 1909.

**FOSTER, SIR GEORGE EULAS** (1847– ), Canadian statesman, was born in Carleton co., New Brunswick, Sept. 3 1847. After a brilliant career in the university of New Brunswick, and also at Edinburgh and Heidelberg, he returned to Canada and taught in various local schools, eventually becoming professor of classics and ancient literature in a local university. In 1882 he became Conservative member for King's co., New Brunswick, in the Canadian Parliament; in 1885 entered the Cabinet of Sir John Macdonald as Minister of Marine and Fisheries; and in 1888 became Minister of Finance, which position he held until the defeat of his party in 1896. He represented York, New Brunswick, 1896–1900, and from 1904 sat in the Dominion House of Commons as representative for North Toronto. He was appointed Minister of Trade and Commerce in the Borden administration, 1911, and upon the formation of the Union Government in 1917 retained the portfolio. A brilliant debater, a thorough believer in tariff protection for Canadian industries and preferential trade within the British Empire, he made a series of speeches in Great Britain in 1903, on the invitation of Mr. Chamberlain, in support of Imperial trade preference. He was one of the Canadian representatives to the coronation of King George and Queen Mary, June 1911, and was Canadian representative on the Dominions Royal Commission appointed by King George, 1912. He was sworn of the Imperial Privy Council in 1916, and the same year was appointed one of the four representatives of Great Britain to the Economic Conference of the Allies at Paris. In 1918 he was created K.C.M.G., and in 1920 was head of the Canadian delegation to the first assembly of the League of Nations at Geneva, being subsequently elected vice-president of the assembly.

**FOUILLÉE, ALFRED JULES ÉMILE** (1838–1912), French philosopher (*see* 10.737 and 18.250), died at Lyons July 16 1912.

**FOWLER, WILLIAM WARDE** (1847–1921), British classical scholar and ornithologist, was born at Langford Budville, Som., May 16 1847, the second son of John Coke Fowler, stipendiary magistrate of Swansea. He was educated at Marlborough and at Lincoln College, Oxford, graduating first class in *literae humaniores*

*ores* 1870, and being elected to a fellowship at his college two years later. From 1882 to 1904 he was sub-rector under W. W. Merry. In 1909–10 he was Gifford lecturer at Edinburgh. He combined exact scholarship with a living interest in the ancient world which made his classical studies, especially of Roman history, both readable and popular. They included a *Life of Julius Caesar* (1892); *The Roman Festivals of the Period of the Republic* (1899); *Social Life at Rome in the Age of Cicero* (1909); *The Religious Experience of the Roman People* (1911) and *Roman Ideas of Deity* (1914). Equally delightful were his writings on birds, *A Year with the Birds* (1886); *Tales of the Birds* (1888); *Summer Studies of Birds and Books* (1895); *More Tales of the Birds* (1902) and many occasional papers. His latest work included *Essays in Brief for War Time* (1916) and studies of Virgil's *Aeneid*. He died at Kingham, Oxon., June 14 1921.

**FOX, JOHN** (1863–1919), American writer, was born at Stony Point, Ky., Dec. 16 1863. He graduated from Harvard in 1883. His books, which depict the life of the Kentucky mountaineers, include *A Mountain Europa* (1894); *A Cumberland Vendetta* (1895); *Hell-for-Sartain* (1896); *The Kentuckians* (1897); *Crittenden* (1900); *Bluegrass and Rhododendron* (1901); *The Little Shepherd of Kingdom Come* (1903); *Christmas Eve on Lonesome* (1904); *Following the Sun Flag* (1905); *A Knight of the Cumberland* (1906); *The Trail of the Lonesome Pine* (1908) and *The Heart of the Hills* (1913). He died at Big Stone Gap, Va., July 8 1919.

**FRACTURES,** in surgery (*see* 4.201).—Further improvements in the treatment of fractured bone have been made, especially as the result of experience during the World War.

Before treatment of any fracture is undertaken, it is essential that an accurate knowledge of its detail be obtained. A diagnosis is made by X-ray photographs taken in two places at right angles to each other. The result, too, of treatment is noted by this means, and the progress of union ascertained by testing at intervals the degree of mobility between the fragments under the X-ray screen.

A fracture in which there is displacement of the fragments is always a serious injury, and the treatment is often difficult. The first aim of treatment is to restore the bone to its original anatomical alignment (reduction). The second is to keep this alignment, and at the same time to maintain the function of the muscles and joints of the limb. The two are interdependent, as the return of function depends to a very great extent on the accuracy of the reduction.

Two main methods of treatment are available in order to restore the alignment of the bone: non-operative and operative.

*Non-Operative Treatment.*—One of two methods may be chosen, depending on the site and nature of the fracture:—(*a*) Immediate reduction by forcible traction and manipulation, and maintaining the restored position by appropriate splinting. (*b*) Gradual reduction. In this method continuous extension (traction by means of weights) is applied to the limb in order to cause relaxation of the muscles. The fragments will then tend to resume their normal position, or can be more easily manipulated into such position.

*Operative Treatment.*—The object of operative treatment is to expose the fractured ends of bone, to replace them accurately in their original alignment, and in most cases to secure them in this position. The best means by which to fix the fragments is still *sub judice*, but many materials have been used, notably bone grafts, metal plates and screws, bone pegs, metal wire, etc.

The bone graft has been widely used during the past few years. Its widest application is probably in cases where there is actual loss of bone substance, and the graft is used as a medium round which new bone may grow (old compound fractures). In the simple fracture its function is that of an internal splint to secure the fragments after reduction, and its value here is limited at present to the less severe cases. In the severe fractures the best method so far of securing a firm fixation is by means of a metal plate and screws (Arbuthnot Lane). Metal wire and bone pegs are valuable only in cases of injury to the smaller bones. When the fracture is in the neighbourhood of or involving a joint, as a rule the fragments are replaced in position only.

*After-Treatment.*—By whatever method the alignment of the bone is restored, the limb is splinted so that it is possible to commence at an early date general massage of the limb, and active movements of the joints in the neighbourhood of the fracture.

The splinted limb is suspended from an overhead frame-work. By a system of weights and pulleys a very wide range of movement is permitted to the patient, while the injured limb is maintained immobilized. This arrangement facilitates also the nursing of these often difficult cases. For fractures of the lower limb various forms of ambulatory splints have been devised to permit of walking at an early stage in the treatment.

*Compound Fractures.*—In the case of compound fractures, some by reason of their situation are necessarily either directly or indirectly compound, *e.g.* a fracture of the mandible (lower jaw), or certain fractures of the base of the skull. The majority of compound fractures, however, occur in the limb bones. These may be caused by some violent force striking the limb, lacerating the skin and soft structures surrounding the bone, and at the same time fracturing the bone. Dirt, clothing, etc., are thus carried into the wound. Many thousand such cases occurred in the war from the effects of gunshot. On the other hand, a bone may be broken, and afterwards, from the continuation of the violence or from the crumpling of the limb, the sharp end of one of the fragments may be forced through the muscles and skin.

In either case the important point is that the injured tissues have been exposed to infection by micro-organisms and provide in their damaged condition very favourable soil for their growth. If infection (sepsis) gains a foothold, the condition is a serious one always, and at the worst may involve loss of the limb or even life, at the best a long and tedious treatment.

The first object in the treatment of a compound fracture is to convert it into a simple one. This is accomplished by an excision of all lacerated tissue, and closure of the wound (primary suture). The treatment is then continued as for a simple fracture. In a large number of cases during the World War, the wound had become infected before continuous treatment was possible. The primary consideration, therefore, was to deal with the sepsis, and the results of septic absorption.

As the result of experience certain principles were evolved, which advanced the treatment of these serious cases to a marked degree. The main principles may be briefly summarized as follows:—

(1) To obtain an accurate reduction of the bone fragments and coincidently of the soft structures, thus enabling them to combat at a greater advantage the effects of sepsis.

(2) By efficient splinting to ensure a complete immobilization of the whole limb; the chance is then given for a natural barrier against the spread of infection to be formed in the limb.

(3) To use a simple, cleansing, and as far as possible painless treatment for the wound itself. Of the many treatments tried, it is probable that the Carrel-Dakin method of intermittent irrigation is in these respects the best.

(4) To close the wound when it has become bacteriologically clean (secondary suture). (F. D. S.)

**FRAMPTON, SIR GEORGE JAMES** (1860– ), English sculptor, was born in 1860. He received his art training at the Royal Academy schools, where in 1887 he obtained a gold medal and the travelling studentship, and later under Mercié in Paris. In 1884 he exhibited "Socrates Teaching," but after some years tried experiments in other mediums than marble, with successful results. Frampton was elected A.R.A. in 1894, and received many important commissions, including a memorial statue of Queen Victoria for Calcutta; the sculpture on the exterior of Lloyds, London; the sculpture on the Glasgow art galleries; and the figures on the spire of St. Mary's, Oxford. He was elected R.A. in 1902, and in 1908 was knighted. His later works include busts of King George and Queen Mary for the Guildhall; "Maternity" (1905); a full-length seated statue of the Marquess of Salisbury (1907); the "Peter Pan" statue in Kensington Gardens (1912) and the Edith Cavell monument (1920). He also produced various fine designs for medals, including those commemorating the C.I.V. force and the coronation.

**FRANCE, ANATOLE** (1844– ), French critic and novelist (*see* 10.775), produced three new novels after 1910: *Histoire Comique* (1911); *Les Dieux ont soif* (1912) and *La Révolte des Anges* (1914). He also wrote a play, *La Comédie de celui qui épousa une femme muette* (1912). *Le Petit Pierre*, a sequel to his early book *Le Livre de mon Ami*, appeared in 1918. These books, with two war utterances, *Sur la voie glorieuse* (1914) and *Ce que disent nos morts* (1916), make up his later literary output. On Oct. 11 1920 he was married in Paris to Mlle. Emma Laprévotte. He was awarded the Nobel Prize in literature in 1921.

**FRANCE** (*see* 10.375*).—The convulsions of the World War deeply disturbed the work of the statistical machinery of France, both central and local. Ten departments of the country were for several years in enemy occupation, and the result was that in 1921 no proper statistical information as to the population and its activities during that period was obtainable. In many places local records had been destroyed, and the central statistical bureau was deprived of many of its workers.

*Population.*—The quinquennial census, which was first taken in 1831, was interrupted in 1916 by the war. It was again taken in March 1921. The last previous complete census returns, those of 1911, showed the total pop. to be 39,604,992, including 1,152,096 foreigners, a slight decrease as compared with the 1906 figures. The organized efforts made to stem the fall in the birth-rate and to reduce infant mortality by the granting of preferential treatment to large families and by hygiene had not met with the success they deserved, and the losses in war-time came to aggravate the problem.

The census taken in March 1921 (provisional figures) gave France a total pop. of 37,499,394, of whom 1,415,128 were foreigners. These figures do not include the French troops abroad in the occupied territories of Germany, nor the French forces in the plebiscite zone of Upper Silesia and the mandate territory of Syria, nor do they include the pop. of the recovered provinces of Alsace and Lorraine. As the distribution of parliamentary representation is based upon pop., it should be noted that the two constituencies of Aveyron contain 181,821 and 145,942 French inhabitants; the two divisions of the Bouches-du-Rhône have 507,224 and 187,715; the two of Calvados, 229,478 and 148,061; the two of the Loire-Inférieure, 331,630 and 314,316; the Maine-et-Loire 253,395 and 219,209; the Pas-de-Calais, 545,023 and 406,572; the Basses-Pyrénées 219,193 and 161,686; and the four divisions of the Seine have as French pop. 955,539, 785,232, 996,174 and 1,440,652. Table 3 gives the details of the departmental population. Including Alsace-Lorraine, the census showed a total pop. of 39,402,739, of whom 1,550,449 were foreigners.

Male pop. in 1911 numbered 19,254,444; the female pop. was 19,937,689, an excess of females over males of 683,245. This preponderance of females in France has been steadily more marked since 1886. For every 1,000 males there were 1,014 females in 1891, 1,033 in 1901 and 1,035 in 1911, when the proportion was 50·87 females, as compared with 50·80 in 1901. The growth in female population is due both to increased female births and to increased female longevity. Congestion in urban areas at the expense of agricultural districts was a marked feature of 1911 returns, and it was anticipated that this movement would be shown even more clearly in 1921 returns.

TABLE 1.—*Towns of over 100,000 Inhabitants.*

| | 1906 | 1911 |
|---|---|---|
| Paris | 2,711,931 | 2,847,229 |
| Lyons | 430,186 | 523,796 |

* *These figures indicate the volume and page number of the previous article.*

The distribution of the active population in 1911 according to occupation showed that, in spite of the townward movement, agriculture was the chief concern of the country. During and since the war it is suspected that industry has made heavier demands upon labour. Table 4 gives 1911 figures (in thousands).

TABLE 4.—*Occupation Statistics.*

| Occupation | Males | Females | Total |
|---|---|---|---|
| Agriculture | 5,279 | 3,238 | 8,517 |
| Manufactures | 4,951 | 2,535 | 7,486 |
| Trade | 1,218 | 835 | 2,053 |
| Liberal Professions and Public Services | 888 | 337 | 1,225 |
| Domestic Service | 158 | 771 | 929 |
| Soldiers, Sailors and Fishermen | 718 | 3 | 721 |
| | 13,212 | 7,719 | 20,931 |
| No Occupation | 6,042 | 12,219 | 18,261 |

The number of foreigners in France, which had decreased from 1,130,211 in 1891 to 1,038,871 in 1901 (the proportion per 10,000 inhabitants falling from 297 to 269), increased in the period 1901–11 to 1,159,835, or 296 per 10,000. The principal nationalities represented were, in 1911: Italians, 419,234; Belgians, 287,126; Spaniards, 105,760; Germans, 102,271; Swiss, 73,422; British, 40,378; Russians, 35,106. The large number of Italians and Belgians in France was due to the labour requirements of the textile industries in the north and of the mineral fields in the east.

The only official vital statistics, of more recent date, available in 1921 are partial and approximate in character. They relate to 77 out of 87 departments (the other 10 having been invaded), and are based upon the *bulletins d'état civil*, or ordinary registration statistics, and not upon the more satisfactory data of the general census returns. Subject to these reservations, the figures of the years 1911–9 are summarized in Table 5.

TABLE 5.—*Vital Statistics.*

| | Population (in thousands) | Marriages | Births | Deaths |
|---|---|---|---|---|
| 1911 | 33,085 | 255,036 | 602,978 | 647,284 |
| 1912 | 33,065 | 253,534 | 608,690 | 579,175 |
| 1913 | 33,095 | 247,880 | 604,811 | 587,445 |

| 90 Departments † | 41,476,272 | 333,241 | 424,668 | 356,722 |

* Increase due to the influx of refugees from the invaded departments and from foreign countries.

† Including Moselle, Upper and Lower Rhine (Alsace-Lorraine).

Table 5 shows the great decline of the birth-rate due to the war, and its rapid recovery in 1918 and 1919. The high mortality in 1918 is to be attributed to the epidemic of influenza.

Divorces in the 77 departments numbered 12,344 in 1913, decreased until 1915, but increased to 8,121 in 1918 and to 11,657 in 1919. During the first six months of 1920 the total was 9,614, more than double the figure for the corresponding period of 1919.

The number of recruits of the 1921 class who were passed as fit for army service was 272,000 (including Alsace and Lorraine), and their proportion to the total of young men liable for service with this class was 78%, a higher figure than that of the 1913 class. The strictness of the medical examination is shown by the number of *ajournés* (recruits expected to come up to the physical standard at some future time), which was 61,943. The proportion between the corresponding number of births and the number of young men attaining the age for military service reached 75%, for the first time, in 1921. It had been rising slowly for the past 20 years but had not previously gone beyond 73 per cent. Reckoning the actual number of men passed by the doctors, and the average number of *ajournés* to be subsequently added, the 1921 class constitutes a distinct improvement on its predecessors. The privations endured during the war do not appear to have had such bad results as were feared in regard to the physical development of the youth of the country. This is attributed by the military authorities to three causes: the decrease in the consumption of spirits, the influence of athletic sports, and, to a certain extent, a better knowledge of sanitary and dietary conditions among the peasantry.

An official report on crime statistics in France from 1914–9 shows that while the total number of crimes and offences was below the average, there was a distinct increase of criminality among women and minors under 18 years of age. Before the war, out of every 100 persons convicted 12 were women and 5 minors, but during the war period these proportions rose to 30 and 14 respectively. Abortion and infanticide more than doubled.

In regard to minor offences, only thefts show an increase (62,869 in 1919 against 36,401 in 1913). There was a considerable decrease in the prosecutions for begging and being without visible means of subsistence. Common assaults decreased by more than 50%, and there was a similar diminution in all offences generally due to drink. The report attributes this result to legislation against drunkenness and the prohibition of absinthe. The figures, however, are not an exact reflection of the situation, the operations of justice having been greatly hampered by circumstances.

*Constitution.*—The only constitutional change made in France between 1910 and 1921 was the adoption of a new system of voting at parliamentary general elections. Previously, the seats went to the candidates receiving the highest number of votes, as in England, with this difference, that if no candidate received an absolute majority—that is to say, at least one more than half the total votes polled—a secondary election, known as the *scrutin de ballotage*, became necessary, on which occasion an actual and not an absolute majority was sufficient.

There are two varieties of the majority system. One consists of dividing the constituency into sections, each of which elects one member. The other may consist of the election of a list of as many candidates as there are seats in the constituency (in France, the department). The first of these systems is known as the *scrutin d'arrondissement* and the second as the *scrutin de liste*. For many years there was an agitation in France against the prevailing system (*scrutin d'arrondissement*) because it was regarded as unfavourable to the general principles by which politics should be guided. A deputy elected by a comparatively small body of voters often became the mere mouthpiece of local interests and was inclined to put those of the nation in the background. It eventually became evident that the *scrutin d'arrondissement* was definitely condemned. Parliament, however, did not replace it by the *scrutin de liste* pure and simple, because it was felt that this system was too absolute and too hard on minorities. In a department, for instance, returning 10 members and having 50,000 electors, a list which obtained one vote less than the other ran the risk of not being represented at all and losing all 10 seats to the opposition. The result would be something very much like oppression of the minority, and there might be a temptation for the minority to put forward its claims in illegal ways instead of through the constitutional parliamentary channel. Parliament, therefore, in 1919, abolished the majority system of voting and adopted a compromise between the proportional voting system and the other. The present system is a majority one, tempered by concessions to minorities, or it might be described as a proportional system giving a kind of bonus to majorities.

Two terms require definition before any explanation of the French electoral system can be given—the "electoral quotient" and the "average." The former is the figure obtained by dividing the number of votes cast by the number of seats to fill. The average of a list is, as the word implies, the number of votes cast for the list divided by the number of candidates. A list obtains as many seats as the number of times the electoral quotient is contained in the average of the list. As an example take the hypothetical case of a department returning five members. There are three lists of candidates—Conservative, Radical and Socialist—and the voting is as follows:—

| Conservatives (5 candidates) | | Radicals (4 candidates) | | Socialists (3 candidates) | |
|---|---|---|---|---|---|
| A | 15,000 | F | 12,000 | L | 9,500 |
| B | 14,500 | G | 11,500 | M | 9,000 |
| C | 14,000 | H | 11,000 | N | 8,500 |
| D | 13,500 | J | 10,500 | | |
| E | 13,000 | | | | |
| Total | 70,000 | Total | 45,000 | Total | 27,000 |
| Average | 14,000 | Average | 11,250 | Average | 9,000 |

The total votes cast being 34,250, the division of this number by 5 (the number of seats to fill) gives the electoral quotient, 6,850. The average of the Conservative list contains this quotient twice (13,700) with 300 over. The average of the Radical list contains the quotient once, with 4,500 over, and the Socialist list contains the quotient once, with 2,250 votes over. The first list thus gets two seats, the second one and the third one, and these seats go to the candidate having obtained the greatest number of votes. Consequently the candidates returned are A, B, F and L. The allotment of the fifth

seat, which is made in virtue of the highest average and not the quotient, will be explained further on. It will be observed that L, who receives only 9,500 votes, is declared elected, while D, with 13,500, is unsuccessful. This apparent anomaly is explained by the theory that party principles are of more importance than persons. D's votes count towards the success of his list, which obtains two seats while L's has only one, and there is no obligation to consider the personal feelings of D.

As above mentioned, the proportional system is tempered in France by bonuses offered to majorities. Any candidate polling more than half the total votes cast is elected, and in his case there is no question of quotients or averages. Consequently, if all the candidates on one list obtain more than half the total votes cast, the list is elected *en bloc*. This happened in some 20 constituencies when the first general election took place under the new law in 1919. If any seats are left over after the quotient operation has been worked out, they go to the lists having the highest average. In the example given above, the Conservative list has the highest average, 14,000. It, therefore, obtains the fifth seat, and C is declared duly elected. This provision sometimes produces surprising results. In a department returning six members, each of the three lists may have the quotient once with a large number left over; and if the average of list No. 1 be only a single vote more than that of list No. 2, No. 1 list gets all the three seats left over. This was illustrated in the department of the Gard, where the Conservative list obtained 4 seats and the Radicals only 1, although the latter polled nearly as many votes as their adversaries.

When a candidate on a list obtains an absolute majority, this is so much net profit for his list, as his votes continue to count for the average. When there is only a single candidate, he may be elected either on an absolute majority or if he has more votes than are cast for the candidates elected on the strength of the quotient. It may also happen that two lists may each get three times the quotient although there are only five seats to fill. In such a case the seats go to the highest average. In the Haute-Vienne, a list which obtained the quotient three times did not get a single seat. Three candidates on the other list were elected by absolute majorities, and the two remaining seats went to this list in virtue of the higher average.

In addition to the bonus to majorities, and the maintenance of the absolute majority (thus facilitating coalitions which the law was designed to prevent), the French system contains another anomaly—the maintenance of the old system for by-elections. These are decided exactly as they were before the law of 1919, with a *scrutin de ballotage* if the first ballot does not give an absolute majority.

France had not yet in 1921 accorded the vote to women, although the Chamber of Deputies, in May 1919, voted a bill recognizing the full political rights of Frenchwomen. At the annual Women's Suffrage Congress, held in Paris in May 1921, the reports from all the provincial organizations showed that public opinion was moving steadily in favour of the change.

*Church and State.*—After an interval of 17 years, diplomatic relations between France and the Holy See were resumed in May 1921, when M. Jonnart, the French ambassador extraordinary, presented his credentials to the Pope. It may be useful here briefly to relate the circumstances which attended the estrangement between the Church and its "eldest daughter." M. Loubet, President of the French Republic, paid an official visit to the King of Italy at Rome from April 24–28 1904, without taking any official notice of the Holy See. On April 28, Cardinal Merry del Val, Papal Secretary of State, protested against the visit of the head of a Catholic State to the Quirinal. The first news of this protest was given by M. Jaurès in his paper, the *Humanité*, on May 16, and on the 21st the anti-clerical premier, M. Combes, who probably had a good deal to do with the disclosure, recalled M. Nisard, French ambassador to the Vatican. On July 30 the Government also recalled its *chargé d'affaires*, Baron de Courcel, in consequence of utterances by Mgr. Geay, Bishop of Laval, and Mgr. Le Nordez, Bishop of Dijon, which showed that certain provisions of the Concordat were interpreted differently by Church and State. The relations between France and the Holy See were thus broken off by the French Government acting in the exercise of its prerogatives. The position was unchanged at the time of the outbreak of the World War, but there had long been a growing conviction in France that the estrangement was not only unnecessary but harmful to French interests, and that, if only in virtue of the principle expressed in the saying "*Les absents ont toujours tort*," it was a mistake for France, who still considered herself the protector of Catholic missions in the East, to be without admission to so unequalled a political observatory as the Vatican. This feeling was strengthened in the course of the war by the attitude of the French clergy, who espoused the national cause in the most whole-hearted manner. Thousands of priests of military age served in the ranks and set a magnificent example to their fellow soldiers. The diocese of Lyons alone lost 147 priests and divinity students. The French bishops, especially in the invaded area, showed great courage and fortitude under the most trying circumstances. Amid the perils and hardships of war, innumerable French citizens, combatants and non-combatants alike, discovered that the consolations of religion were not an empty phrase. When the war came to an end, anti-clericalism as a political force had ceased to exist in France, and, after the elections in 1919, there was no longer any valid reason for adhering to the policy of M. Combes. In March 1920 M. Millerand's Cabinet brought in a bill for the reëstablishment of the French embassy to the Vatican. The bill was voted by the Chamber of Deputies on Nov. 30 by 391 to 179. Up to the beginning of June 1921 the bill had not passed the Senate, but the Government, headed by M. Briand, felt justified in acting upon it without further delay and resuming the relations broken off by his predecessor in 1904. By a curious coincidence, M. Combes died on the very day on which this was done.

Apart from considerations of foreign policy and expediency, there were two strong arguments in support of M. Briand's action. The motive for the recall of the French ambassador in 1904 was the protest raised by Pope Pius X. because the President of the French Republic ignored him during his official visit to the Quirinal. The Pope's successor (Benedict XV.) stated on May 23 1920 in his encyclical "Pacem Dei munus pulcherrimum" that henceforth no protest would be raised against visits by heads of Catholic States to the Quirinal. The primary cause of the conflict was thus removed. The second cause resided in differences of interpretation of the Concordat, but as this instrument was abolished by the separation of Church and State in France, there could be no such differences in future.

*Education.*—During the period 1910–21 the State educational system remained uniform throughout France, varied only by the changes in the programme which take place about every 10 or 12 years in accordance with what are considered to be the requirements of succeeding generations of scholars. Many French experts reproach the university authorities with an excessive tendency to lower the level of secondary education in response to the desires of parents, who, in general, seem to favour a shortening of the period of study and the hastening of the time when their sons will be able to begin their careers. There is some reason to fear that the intellectual level of the country may to some extent be sacrificed to utilitarianism. In the years immediately following the war, the leaning towards the modern science side of instruction was very marked. At the beginning of the 1920 winter term the only vacancies in the Paris *lycées* for boys were on the classical side.

In addition to the ordinary degrees, French universities are allowed to grant diplomas in special subjects, such as applications of science and commercial science. Certificates for knowledge of French are also issued to foreigners who have gone through a course of study of the language. The special certificates granted by French universities in 1920 were: Paris, 172; Aix and Marseilles, 12; Algiers, 4; Besançon, 11; Bordeaux, 37; Caen, 31; Clermont, 6; Dijon, 6; Grenoble, 537; Lille, 12; Lyons, 143; Montpellier, 50; Nancy, 160; Poitiers, 9; Rennes, 10; Strasburg, 19; Toulouse, 127.

(G. A.; G. A. R.)

## Agriculture and Industry

*Agriculture.*—Agriculture still remains the main occupation of the French. At the outbreak of war over 60% of its labour was mobilized and invasion robbed the country of the resources of the richest agricultural provinces. These causes, together with shortage of phosphate manures, brought about a very serious falling-off in production. Table 6 gives the statistics of the chief crops:—

Table 6.—*Principal Crops (in thousand quintals).*

| | 1913 | 1916 | 1917 | 1918 | 1919 |
|---|---|---|---|---|---|
| Wheat | 86,919 | 53,767 | 39,488 | 61,435 | 48,438 |
| Maslin (mixed rye and wheat) | 1,490 | 1,079 | 879 | 959 | 927 |
| Rye | 12,714 | 8,471 | 6,995 | 7,349 | 7,070 |
| Barley | 10,457 | 8,331 | 8,966 | 5,968 | 5,143 |
| Oats | 31,626 | 40,223 | 34,462 | 25,629 | 24,429 |
| Maize | 5,430 | 4,295 | 4,118 | 2,479 | 2,992 |
| Millet | 186 | 153 | 319 | 89 | 199 |
| Sarrasin (buckwheat) | 3,664 | 2,738 | 3,272 | 3,243 | 2,875 |

The law passed on Oct. 25 1919 formed a Chamber of Agriculture in each department. There are regional offices at Paris, Rennes, Nancy, Bourges, Lyons, Clermont-Ferrand, Bordeaux and Marseilles.

Before the war France was independent with regard to wheat. This is no longer the case, and during the year 1919 she required about 35 million quintals from abroad. The figures for 1919 show a drop of 40% in production since the war. France before the war was third on the list of wheat-producing countries, coming after the United States and Russia. In 1919 she dropped to fourth place behind the United States, India and Canada. During the war the wheat problem was met partly by the purchase of foreign wheat, and also by releasing from the army peasants belonging to the 1888, 1889, 1890, and 1891 classes—about 250,000 men in all; by the use of African labour, prisoners-of-war and tractors. The chief step taken to encourage wheat-growing was the raising of the price of wheat and, from 1915, the direct purchase of the crop by the State. The quintal of wheat had been worth 29·49 francs in 1914. The requisition price was 30 francs until March 1916, and then rose to 33 francs on Aug. 1 1916; 36 francs, April 1917; 50 francs, July 1917; 75 francs, Aug. 1918; 73 francs, 1919. The State sold the wheat to millers in the provinces at 43 francs, in Paris at 31·90 francs. The budgetary cost of this method was 2,500 million francs in 1919.

The area of land under cultivation in 1913, the last complete year before the war, and in 1918, is shown in Table 7.

TABLE 7.—*Land under Cultivation* (*in hectares*).

| | 1913 | 1918 |
|---|---|---|
| Arable land | 23,651,100 | 20,881,480 |
| Meadow land | 4,908,668 | 4,601,480 |
| Grass land | 1,490,870 | 1,476,190 |
| Pasturage (including *pacages*) | 3,648,150 | 4,157,410 |
| Vines | 1,616,621 | 1,566,884 |
| Kitchen gardens | 266,845 | 253,380 |
| Nursery gardens | 960,410 | 801,490 |
| Woods and forests | 9,886,701 | 9,746,719 |
| Uncultivated land | 3,793,450 | 4,549,290 |
| Unclassified land | 2,729,764 | 4,917,896 |
| Total area | 52,952,579 | 52,952,219 |

Statistics for other crops are given in Table 8. With regard to potatoes, France, as a result of the war, has turned from an exporting to an importing country. In 1912 the balance in her favour was about 17 million francs; whereas in 1919 her imports amounted to 128,519,000 francs, and her exports only to 13,727,000 francs.

TABLE 8.—*Other Crops* (*in thousand quintals*).

| | 1913 | 1916 | 1917 | 1918 | 1919 |
|---|---|---|---|---|---|
| Mangold-wurzel | 252,201 | 154,910 | 160,896 | 108,173 | 104,933 |
| Swedes and turnips | 34,540 | 25,173 | 25,318 | 20,451 | 17,780 |
| Cabbage | 82,749 | 55,106 | 57,042 | 52,506 | 40,449 |
| Trefoil, Lucerne sanfoil | 316,432 | 108,864 | 90,344 | 86,581 | 75,151 |
| Green fodder | 186,227 | 111,117 | 91,860 | 83,340 | 59,586 |
| Meadows | 156,914 | 157,218 | 131,291 | 117,908 | 128,156 |
| Potatoes | 135,859 | 87,811 | 109,226 | 65,197 | 77,635 |
| Root artichokes | 17,793 | 14,920 | 15,780 | 10,528 | 11,562 |
| Sugar-beet | 59,393 | 19,886 | 21,085 | 11,424 | 10,830 |
| Beet for distilling | 20,505 | 7,915 | 7,024 | 3,417 | 3,471 |
| Hemp | 219 | 42 | 40 | 68 | 98 |
| Flax | 69 | 41 | 20 | 88 | 69 |
| Hops | 36 | 19 | 17 | 4 | 8 |
| Tobacco | 260 | 146 | 77 | 88 | 141 |

*Live Stock.*—The war had a disastrous effect upon French herds, as is shown by a comparison (Table 9) of the figures at the beginning of 1918 with those of the beginning of 1914.

TABLE 9.—*Live Stock* (*in thousands*).

| | 1913 | 1918 |
|---|---|---|
| Horses | 3,231 | 2,233 |
| Mules | 193 | 139 |
| Asses | 360 | 311 |
| Cattle | 14,807 | 12,251 |
| Sheep | 16,213 | 9,061 |
| Swine | 7,048 | 4,377 |
| Goats | 1,453 | 1,197 |

*Wine.*—War had practically no effect upon the wine-grower, as is shown by the following figures of production, which are given in thousands of hectolitres: 1913, 44,171; 1914, 59,981; 1915, 20,442; 1916, 36,068; 1917, 38,227; 1918, 45,160; 1919, 51,461. The price of ordinary wine was 16 francs the hectolitre in 1914, and it rose in great jumps to 135 francs the hectolitre in 1918. No figures were yet obtainable in 1921 showing the effect upon the wine-growing industry of the disappearance of its best foreign customer, Germany, and of the prohibition legislation in the United States, which had been third on the list of foreign purchasers of champagne.

Statistics with regard to agriculture were in 1921 greatly in arrears. For instance, the latest available figures for the butter industry were pre-war, and many of the figures with regard to the chief crops and wines for 1917, 1918 and 1919 were provisional.

*Industries.—Coal.*—The production of coal and other solid mineral fuels was greatly affected by the World War. The whole of the Valenciennes and part of the Pas-de-Calais mining districts were invaded at the beginning of hostilities, thus depriving France of mines which, in 1913, had produced over 18,000,000 tons of coal. In those parts of France which escaped invasion all the younger miners were mobilized, leaving only the men belonging to the territorial forces. This state of affairs continued for some time, but in 1915 the need of an increased output of coal was recognized, and a certain number of miners were recalled from their corps and sent to the mines in the centre and south.

Table 10 gives the total production and the number of persons employed in the mines of France.

TABLE 10.—*Coal Production and Workers.*

| | Tons | Persons |
|---|---|---|
| 1914 (second half) | 7,400,000 | 62,000 |
| 1915 | 19,500,000 | 72,000 |
| 1916 | 21,300,000 | 78,000 |
| 1917 | 28,900,000 | 115,000 |
| 1918 | 26,200,000 | 114,000 |

The decrease in production in 1918 was due to military operations in the Pas-de-Calais coal-fields, where some mines ceased working.

Production during the war period amounted to about 70% of the pre-war output. To make up for the deficiency, large quantities of coal were imported, as shown in Table 11.

TABLE 11.—*Imports of Coal.*

| | Total in tons | From Great Britain | From the United States |
|---|---|---|---|
| 1914 (second half) | 5,346,000 | 4,700,000 | — |
| 1915 | 19,700,000 | 18,900,000 | 145,000 |
| 1916 | 20,420,000 | 18,700,000 | 53,000 |
| 1917 | 17,453,000 | 15,800,000 | 57,000 |
| 1918 | 16,830,000 | 15,300,000 | 17,000 |

The result of the efforts made since the end of the war to bring the damaged French coal-mines back to their former productiveness is shown by the statistics as to the amounts of coal won in 1919 and 1920. In France the totals were 25,274,304 tons in 1920 and 24,476,766 in 1919. In the Saar coal-fields the totals were 9,410,433 tons in 1920 and 8,970,848 in 1919. The number of workers in the pits was 143,405 in 1920 (Dec. 31) and 113,240 in 1919; at the surface, 81,063 in 1920 and 62,832 in 1919. The coal consumed at the mines in 1920 was 3,838,486 tons, or 15% of the output.

The mines in the department of the Nord in Jan. 1921 had regained 43·5% of their pre-war output. At the beginning of 1919 they produced only 1,535 tons; a year later it was 122,055 tons, and in Jan. 1921 it was 353,297 tons. Even the Pas-de-Calais mines, comprising the Lens and Liéven pits, which were actually on the battle-front for years and suffered worse than any others, had been nearly cleared of water in the spring of 1921.

Table 12 gives the output of the French coal-fields for Jan. 1921, and affords some idea of their comparative importance.

TABLE 12.—*Details of Coal Output, Jan. 1921.*

| District and Coal-field | Coal tons | Lignite tons |
|---|---|---|
| Arras (Pas-de-Calais) | 579,606 | — |
| Douai (Nord and damaged mines in Pas-de-Calais) | 250,243 | — |
| Saint-Étienne (Loire) | 219,329 | — |
| Lyons (Blanzy, La Mure) | 153,335 | 617 |
| Clermont-Ferrand (Saint-Eloy, Brassac) | 83,324 | 74 |
| Alais (Alais, Graissesac) | 93,167 | 2,932 |
| Toulouse (Carmaux, Aubin) | 105,667 | 708 |
| Marseilles (Fuveau) | 3,118 | 61,226 |
| Nantes (Vouvant, Maine) | 5,131 | — |
| Bordeaux (Ahun) | 2,497 | 1,925 |
| Nancy (Ronchamp) | 5,136 | 374 |
| Strassburg (Moselle) | 255,471 | — |
| Totals | 1,756,024 | 67,856 |

*Industrial Fuel.*—Before the war Germany supplied France with 78% of her imports of the coke she required for her iron-works and other metal industries. Germany was thus able to alter the price of her coke according to circumstances, thereby benefiting her own iron and steel manufactures and making it increasingly difficult for France to compete with her in metal exports. On the average, the French ironmaster paid for coke 13 fr. a ton more than his German and 12 fr. more than his English rival.

Reckoning 12 tons of coke per ton of pig-iron, the relative expenditure for fuel in the production of a ton of pig-iron was in 1912:—France 36 fr.; Belgium 29 fr.; Germany 22 fr.; England 20 fr.

As regards the prices of coal and coke—a question of primary importance to the national industry—the position of France at the time of the war was that home coal at the pit-head cost about 40 % more than in England and 20 % more than in Germany. As about one-third of the quantity consumed in France had to be imported, the average price of coal, 19 fr. a ton, reckoning that of imports, was 2 fr. a ton (12 %) higher in France than in Belgium, 5 fr. (36 %) higher than in Germany and 7 fr. (60 %) higher than in England.

In the period following the Armistice the fuel problem was temporarily solved by the quantities of coal which Germany was compelled to deliver, and also by imports of coal from the United States, which became larger and larger as the supplies from Great Britain dwindled in consequence of miners' strikes and the necessity of stopping or limiting exports. In 1921 the position could only be regarded as uncertain, the supply of coal at reasonable prices to French industries being largely dependent upon the political relations between France and Germany.

*Iron.*—As the result of the war and more immediately of the invasion of the Briey district, the output of iron ore was at first much reduced. The figures are given in Table 13.

TABLE 13.—*Iron (in tons).*

| | Output | Imports | Exports |
|---|---|---|---|
| 1914 (second half) | 370,000 | 701,486 | 4,828,591 (whole year) |
| 1915 . . . | 620,000 | 271,159 | 94,863 |
| 1916 . . . | 1,680,000 | 627,604 | 74,561 |
| 1917 . . . | 2,034,000 | 507,908 | 126,532 |
| 1918 . . . | 1,572,000 | 118,610 | 68,346 |

Imports of iron were chiefly from Spain and Portugal, and practically the whole of the exports to England.

In 1920 France produced 13,871,137 tons of iron ore, 23,145 workers being employed in the process. The figures for 1919 were respectively 9,430,000 tons and 19,558 workers. In each case the Lorraine output is included. Pre-war French territory produced 5,800,000 tons. The Lorraine contribution rose from 7,127,000 tons in 1919 to 8,074,989 tons in 1920, this quantity being still considerably below the pre-war level. In round figures, France and Lorraine combined were producing at the end of the year 1920 about 30,000,000 tons less than their pre-war output.

*Steel.*—In 1913 France took fourth place on the list of steel-producing countries, her output being 5,093,000 tons, or 6·8 % of the total. She imported 106,900 tons, exported 477,300 and consumed 4,722,600. Out of the 5,093,000 tons 3,592,000 represented finished products.

The occupation of large tracts of the country by the enemy immediately reduced the steel output by about 60 %, but a great effort was put forward to make good the loss. Many new steel-works were constructed, chiefly in the centre, and existing works modernized their plant so as to contribute as much as possible to the production of the steel so urgently needed for the manufacture of artillery and for other military purposes. The number of new steel-works thus brought into being by the necessities of national defence exceeded 250, with a total capacity of 1,900,000 tons. As many of these new establishments took the place of others which were either worn out or unsuitable to new conditions, the increase in the national output of steel was estimated at not more than 950,000 tons a year.

*Other Minerals.*—Table 14 shows the output of ores other than iron during the second half of 1914 and the four following years.

TABLE 14.—*Output of Other Ores (in tons).*

| | 1914 (2nd half) | 1915 | 1916 | 1917 | 1918 |
|---|---|---|---|---|---|
| Gold . . . | 12,469 | 13,077 | 23,518 | 24,343 | 6,155 |
| Zinc, Lead, Silver | 12,839 | 23,778 | 34,295 | 38,125 | 25,087 |
| Copper and Tin . | 40 | 95 | 1,057 | 1,377 | 811 |
| Antimony . . | 380 | 6,353 | 19,037 | 19,453 | 10,020 |
| Manganese . . | 1,870 | 10,324 | 10,807 | 11,589 | 9,871 |
| Tungsten . . . | 6,061 | 6,062 | 7,289 | 8,548 | 7,414 |
| Iron Pyrites . . | 51,421 | 196,606 | 219,371 | 280,797 | 260,310 |

France produces more bauxite ores, from which aluminium is obtained, than any other country. Her output in 1913 was 309,294 tons, of which she exported 65 per cent. The United States produced 213,605 tons, Great Britain 6,153 tons and Italy 6,952 tons. Germany was dependent on France for 95 % of her imports of these ores. In addition, a large part of the French ores exported to Switzerland found its way to Germany in the shape of aluminium.

During the war the French output of bauxite dropped to 56,522 tons in 1915, advancing to 106,200 tons in 1916 and 120,916 tons in 1917. In this period the United States made great strides and reached an output of 568,690 tons in 1917—nearly twice the quantity produced in 1915.

In regard to aluminium, France produced 13,500 tons, or 26 % of the world's output (63,700 tons), in 1913. She exported about half this quantity. The production of aluminium was so greatly stimulated during the war that it rose from 65,790 tons in 1913 to 176,000 tons in 1917. This increase was, of course, chiefly due to metallurgical researches which showed that aluminium could be adapted to many new uses. The curious alloy known as *duralumin*, which automatically tempers itself in course of time, was one of the most remarkable results of these researches.

France has very little copper ore, and the output of her colonies has been insignificant. The principal mines, Aïn Barbor and Akhaldes, both in Algeria, produce about 5,000 and 2,000 tons a year respectively. French metallurgists, however, have been very successful in transforming the crude metal into the finished and half-finished forms of copper and brass required by various industries.

The war deprived France of 95 % of her copper, through the enforced stoppage of the foundries at Givet (Compagnie Française des Métaux) and Briache-St.-Vaast (Pas-de-Calais). Measures were immediately taken to meet the deficiency. Large foundries were built, among them being one, under the control of the Ministry of Munitions, having an annual capacity of 15,000 tons of bars and 20,000 tons of sheet brass and copper. Considerable extension was given to the electrolytic process of copper-refining, which, before the war, was represented only by two or three small establishments with a total annual output of 2,400 tons. France now (1921) has three large electrolytic copper-works, at Pauillac (Gironde), St. Tour and Le Palais, with a total production of 25,000 tons.

The net result of the war was a smaller increase in the output of metallic copper, due to improved processes, and a very large increase in sheets, bars, wires and tubes. The capacity of the French foundries in 1919 was estimated at 170,800 tons a year of sheet copper and brass, as compared with 31,600 tons in 1913, and 151,000 tons of bars as compared with 21,300 tons in 1913. This production being considerably in excess of home requirements and export possibilities, the return of peace entailed a reduction in the French foundries, especially those producing sheets and bars. Their future appeared to be in the production of aluminium, especially as France possesses large quantities of the ores from which this metal is obtained, whereas the copper smelters are dependent on Japan for most of their raw material.

France produces very little lead ore. Before the war she was importing about 40,000 tons a year, of which 60 % came from Algeria and Tunis. During the war the Tunisian mines were greatly developed as the result of military requirements, and it was estimated that, with peace conditions fully restored, French foundries would be able to reckon on an annual supply of 135,000 tons of ore, representing 80,000 tons of the metal.

The zinc ore produced in France in 1913 amounted to 51,000 tons, and more than three times this quantity was imported; but about half the imports came either from French colonies or from mines controlled by French companies. As in the case of copper, the French zinc smelters do a great deal of transformation work. France, for instance, used to send Belgium twice the weight of sheet zinc she received from Belgium in the form of raw material. The new works erected since the war are expected to give an annual output of 30,000 tons.

*Timber.*—As 18·7 % of French territory consisted of forest land, the supply of timber before the war was considerable, the last annual estimate being 7,912,000 cub. metres, exclusive of firewood. It was nevertheless inadequate to home requirements, and in the same year 1,560,000 tons were imported. The coal-mines in northern France, for instance, derived only one-third of their pit props from their own country, the other two-thirds being imported from Russia and Scandinavia. The war made serious inroads on the national reserves. The enemy held 600,000 ac. of forest land, which became exhausted if not entirely destroyed. The whole war zone comprised 800,000 ac. of forest land, which will have to be replanted to a large extent. It was estimated that France would have to import 5,000,000 or 6,000,000 cub. metres of timber a year for five or six years after the war, quite apart from the requirements of the devastated regions, which were put at 10,000,000 cub. metres.

*Motive Power.*—The motive power produced in France, March 1906, the latest date for which general statistics were available in 1921, was estimated at 3,550,000 H.P., of which 2,604,000 was produced by steam-engines, 773,000 by hydraulic power, and 173,000 by other mechanical means. These figures comprise all agricultural, commercial and industrial establishments, public services and stationary engines used by railways, tramways, etc., but not railway locomotives, steamboats or motor-cars. Between 1901 and 1906 the total energy produced by steam-engines increased from 1,761,000 to 2,604,000 H.P., an increase of nearly 48 per cent. Water-power increased from 575,000 to 773,000 H.P., or 34 per cent.

At the same date there were 13,432 locomotives and 198 motor-driven tractors, representing a total development of about 7,000,000 H.P. on railways and tramways. Exclusive of the navy, there were 1,784 steam-propelled vessels engaged in maritime or pleasure traffic, and 1,169 steam-propelled vessels used for internal navigation. Their total development was estimated at 1,200,000 horse-power. There were, according to the taxation returns, 31,286 motor-cars, developing 337,106 H.P., and 31,869 motor-cycles, developing 60,000 H.P.

The total production of motive power in France in 1906 thus approximated 12,150,000 horse-power.

About 55,000 waterfalls were utilised for the production of power, 53,300 of these being on non-navigable watercourses and 1,700 on navigable rivers and canals. Omitting temporarily unutilized or abandoned waterfalls, the number actually utilised may

be put at 43,500, of which about 42,000 were on non-navigable and 1,500 on navigable rivers and canals. The average output per waterfall was 18 horse-power. Of the total, 3,770 falls were used wholly or partly for the production of electricity. In regard to electrical energy, more recent official statistics show that the total amount of electric power produced by public-service enterprises in 1918 was 1,000,631 kilowatts, and the length of high-tension mains in use was 35,420 kilometres. There were 1,568 private installations producing 261,802 kilowatts.

The departments producing the largest quantities of electrical energy (in kilowatts) were: Seine 286,340, Isère 55,197, Nord 42,141, Seine-Inférieure 39,853, Rhône 27,668, Loire-Inférieure 25,223, Ariège 25,114, Bouches-du-Rhône 24,487, Alpes-Maritimes 22,284, Dordogne 20,951, Meurthe-et-Moselle 20,684.

According to a report presented to the Ministry of Public Works in July 1920 by a special commission appointed in 1919, the total water-power produced in France at the end of 1919 was 1,165,000 horse-power. Machinery in course of erection was expected to give an additional 550,000 horse-power. Plans for the construction of other plant estimated to give an additional 3,000,000 H.P. were already under examination.

M. Hegelbacher, a leading French authority, estimates the total water-power of France, constantly available and available six months of the year, at 4,500,000 and 9,000,000 H.P. respectively, distributed as follows:—

| | Constant | Partial |
|---|---|---|
| Centre, Vosges, Jura | 900,000 | 1,800,000 |
| Northern Alps | 1,000,000 | 2,000,000 |
| Southern Alps | 1,300,000 | 2,600,000 |
| Pyrénées and rest of France | 1,400,000 | 2,800,000 |

Before the war only 13% of the 4,500,000 H.P. was utilized. France takes the third place among European countries in respect of available water-power, the figures (in H.P. per sq. km.) being: Norway, 36·6; Sweden, 20·0; France, 15·9.

One of the most comprehensive attempts ever made in France to utilize water-power was in 1921 being carried out on the Upper Rhône. For many years it was supposed that this river, owing to the speed of its current, could not be used for navigation unless elaborate engineering improvements, the cost of which was prohibitive, were carried out. The development of engineering and hydro-electric science, however, raised the question whether the cost of these works could not be recouped in great measure by the generation of electric power which they would make practicable, and whether the river could not be simultaneously made navigable and become an important source of industrial energy. The answer to these questions will be ascertained when the works on the Upper Rhône are completed. About 100 m. of the river, from Génissiat down to Lyons, is divided into 17 reaches, in most of which it was intended (in 1921) to install plants for generating electricity from the force of the current. The total amount obtainable in this way is estimated at 200,000 horse-power. The heights of the falls vary between 14 ft. 7 in. and 43 ft. 10 in.

An attempt to utilize the tides as a source of power was being planned under Government supervision and with state assistance, in Aber Benoit Bay, on the Brittany coast. This bay possesses natural rocky basins which are regularly filled by the flow and empty themselves with the ebb, and the theory is that the outfall of these basins can be directed to turbines placed permanently under the outfalls, intermediary reservoirs being made so as to regulate as far as possible the outfall from the basins.

*Engineering Industries.*—The French engineering industry has long been inadequate to supply the national requirements in machinery. In 1890 imports and exports nearly balanced, but since then the former have grown much more rapidly than the latter. In 1913 the imports came to 204,800 tons, valued at 297,000,000 fr., and the exports to 82,261 tons, valued at 106,000,000 francs. Marine engines were built by about a dozen firms, and there were between 50 and 60 makers of fixed internal-combustion engines. The fabrication of motors of the Diesel type is on the increase.

France is largely dependent on foreign countries for machine tools. These articles were made in 1913 by about 20 French firms, employing between 3,000 and 3,500 workers. Their output was about 10,000,000 fr., one-fifth of the value of machine tools imported.

The extent to which France was dependent, at the time of the war, on foreign industry for machinery is shown in Table 15, in francs, compiled from the customs returns for 1913.

In a report presented to the Comité consultatif des Arts et Manufactures, three causes for the comparative inactivity of the French engineering industry were set out: (1) inadequate tariff protection, or rather the irregularity of the tariff, as regards raw materials and finished articles; (2) the cost of raw materials; (3) lack of enterprise. The last of these three causes was, according to the report, the most potent of all. Many of the leading firms in the industry appeared to be afraid to branch out into any new direction or even to make any real attempt to modernize their equipment and methods.

The construction of cranes, derricks, movable bridges and other large pieces of machinery required, more especially at seaports and in important factories, for lifting and moving heavy weights has long been one of the weak points in the French engineering industry. Before the war nearly everything of this kind was imported, and 40% of the imports came from Germany. Even in the case of equipment for French Government undertakings most of the machinery of this kind was made in Germany, though it was sold by French firms acting for the German manufacturers, who were enabled, by the export bonuses paid by their Government, and also by their own enterprise, to defy competition. In reality they sold at cost price, making their profit out of the bonuses. Many large contracts for private firms, railways, chambers of commerce, etc., were carried out by German engineering firms under the cover of French names. The plans were generally drawn up by the Germans and recopied by French draughtsmen, and the tenders were made by French firms, including some of high standing. These firms would, no doubt, have preferred to do the whole of the work themselves, but they were handicapped by lack of credits. Tenders for work of this kind do not, as a rule, leave a large margin of profit, and as the risk was borne by the German manufacturer, and the French intermediary was sure of remuneration for his services, the latter preferred to play the secondary part. The result was that French firms confined themselves to weighing-machines and small articles. During the war two or three works were started in the Paris district, but their output was small, and it would appear that in this branch of industry, and, in fact, in large metal work generally, France must be dependent on imports for some years to come.

TABLE 15.—*Machinery (in francs).*

| | Imports | Exports | French Output |
|---|---|---|---|
| Motors of all kinds | 30,000,000 | 11,500,000 | 100,000,000 |
| Machine Tools and Small Machines | 52,000,000 | 16,000,000 | 65,000,000 |
| Agricultural Machinery | 45,275,000 | 14,775,000 | 120,000,000 |
| Motor-cars | 19,250,000 | 229,000,000 | 45,000 chassis |
| Railway Material | 23,335,000 | 6,715,000 | * |
| Textile Machinery | 22,882,000 | 2,539,000 | 20,000,000 |
| Printing and Sewing Machines, Typewriters, etc. | 44,765,000 | 5,363,000 | 23,000,000 |

*650 to 700 engines, 2,000 carriages and 18,000 trucks.

*Textile Industries.*—Before the World War the French textile industry gave employment to more than one-third of the national supply of labour, if we include not only the actual manufacture of materials but the ready-made clothing and lingerie trades. About 40% of all the raw materials imported were utilised by the textile industry, which, unfortunately for France, was very largely concentrated (on account of proximity to the coal-mining centres) in a part of the country open to invasion. The invaded districts contained 81% of the total number of wool spindles, 93% of the flax spindles and 29% of the cotton spindles.

France imports about eight times as much raw wool as she produces, her position in this respect being similar to that of most of the leading European countries, which purchase vast quantities of wool from Australia, Argentina, etc., card it, comb it, make it into yarn and finally into materials with which to clothe their millions of inhabitants. Before the war France came fourth in the list of countries producing combed and carded wool and yarns. In 1910 she had 2,700,000 spindles engaged in transforming the wool into yarn, and this branch of her industry was distinctly flourishing. The exports of woollen yarn rose steadily after 1905. In 1913 they amounted to 14 times the value of imports and exceeded £4,000,000. Half of the total export went to Great Britain.

The woollen industry in the Roubaix district, which employed 43,000 hands in 1914, suffered severely during the occupation. The Germans not only removed such machinery as they thought of use to them but also appropriated all the stocks of raw wool, amounting to 989 tons. The total loss to the Roubaix wool industry was estimated at 632,000,000 fr. (1914 value). As the mill structures and workmen's dwellings were spared, it was found possible to resume work sooner than was expected after the war. Some wool-combing works were able to start again in March 1919. At the end of 1920 83% of the productive capacity had been restored in this branch. A parallel recovery occurred in the weaving section, but was subsequently checked by the economic crisis in the autumn of 1920 and the restriction of bank credits and Government advances.

The French cotton industry, the principal centre of which is at Lille, was in a flourishing condition when the war broke out. Its spinning-mills had an annual capacity of 241,000 tons of yarn and its weaving-mills of 165,000 tons of cloth (of which 13,500 tons was available for export). Like the Roubaix woollen mills, the cotton mills in the Lille, Roubaix and Tourcoing districts suffered severely from German depredations and exactions. The losses in Lille were estimated at 126,000,000 fr. and in Roubaix and Tourcoing at 538,000,000 francs. In each centre a strenuous effort was made towards recovery when peace was restored. Lille had half a million spindles working again at the beginning of 1920, and 370,000 at the end of June, this being about 40% of the number in operation before the war. Roubaix and Tourcoing made a similar recovery, though the mill-owners had to contend against difficulties which were not

entirely due to the war. In 1914 the textile factories worked 10 hours a day, but in April 1919 the daily hours of labour in all factories were reduced to eight. This automatically cut down the output of the textile industry by 20%, there being no possibility of a larger production per hour for the machinery. Another difficulty was a shortage in the supply of labour. Many women left the factories as soon as their husbands returned from the war, and their places were taken by children between 13 and 16 years of age.

As regards the consequences of the war to the French flax-spinning industry, it may be sufficient to say that 95% of the mills were in the Lille district. When hostilities ceased, only one mill was in a sufficiently undamaged condition to be able to resume operations in a few weeks. Subsequently the work of restoration made remarkable progress, and at the end of 1920 about 250,000 out of 600,000 spindles were working again. Simultaneously an effort was made to increase the national output of flax, and at the end of 1920 the area under cultivation was 125,000 ac., or more than twice as much as before the war. Of this area 75,000 ac. are in the Nord, 20,000 in Brittany, 15,000 in Normandy, and 12,000 in the Lower Loire.

Armentières with its cotton-cloth and flax mills, Valenciennes and Cambrai with their muslins and handkerchiefs, Reims with its wool-combing and carding, Caudry with its tulle and embroidery, and many other ruined towns had by 1921 made equally gallant efforts to rise from ruin. Wool seemed to have made the best recovery, inasmuch as in Oct. 1920 Roubaix and Tourcoing had regained 85% of the normal output and were employing 93% of the pre-war number of workers. Cotton was not far behind, but flax was estimated to be three years from a return to normal conditions. Old centres of the woollen industry, such as Mazamet, Elbeuf and Vienne, developed considerably during the war, and new ones were established in Lyons and other textile centres, but it seemed probable they would be gradually transferred back to Roubaix, which has the advantage of proximity to the coal-fields and the port of Dunkirk, and of a nucleus of labour accustomed to textile work.

Among the minor textile industries the manufacture of ribbons, which has its chief centre at St. Etienne, deserves mention. It is carried on by about 170 firms, employing 80,000 workers, and its normal annual production represents a value of about 100,000,000 francs. About half of this is exported, principally to Great Britain (56% in 1913). Another important branch of textiles is the manufacture of tulle, lace and embroidery. The principal centres of production are Caudry and Calais (tulle and guipure), Le Puy (ordinary hand-made lace), Normandy, the Vosges, Brittany and Haute-Savoie (lace *de luxe*), and Tarare (tulle curtains). The total output has never been even vaguely estimated, but it is believed to exceed 200,000,000 francs' worth of lace and guipure and 150,000,000 francs' worth of embroidery. Before the war France exported over 60,000,000 francs' worth of machine-made lace a year. Out of 776 tons, 490 went to the United States and 62 to Germany.

*Silk.*—The production of raw silk in its various forms being an industry specially adapted to poor countries with large supplies of cheap labour, France imports nearly the whole of the raw silk she requires for her manufactures. Before the war she took 16% of the world's output and was the second-largest consumer of raw silk in the world, the first place being held by the United States with 37 per cent. Good silk is produced in the Cevennes, but the quantity represents only 10% of the requirements of the French weavers, who are dependant on Italy, China and Japan.

The three centres of the silk-weaving industry in France are Lyons, St. Etienne and Picardy, but the first alone can really be said to count, inasmuch as Lyons produces 99% of the entire annual output. Three-fourths of this consists of pure silk materials and one-fourth of silk mixed with cotton or wool. Its value in an average year is estimated at about £24,000,000 (reckoning the franc at the par exchange value), the exports at £16,000,000, and home consumption at £10,000,000, the balance being made up of £2,000,000 in imports. During the war many silk-weaving looms were used for making woollen materials. Exports of silk were unaffected at first, and actually increased in 1915 and 1916, but declined materially in 1917.

Lyons silks, which are well known all over the world, had an excellent opportunity, during and after the war, of establishing themselves in the United States and S. American markets, in which they had to face German competition before 1914. That this opportunity had not been grasped by 1921 was due, according to French observers, to the extremely individualistic temperament of the Lyons manufacturers, who would not combine for the purpose of acquiring new markets. M. Emmerond Morel, in his report to the Comité consultatif des Arts et Manufactures, says that another condition necessary to progress—the continual introduction of new and improved machinery—is also unobtainable owing to the strong inherited peculiarities of the Lyonnais character, "which is incomprehensible to those who have never come in contact with it."

The manufacture of artificial silk, which began with the Chardonnet process about the year 1890, has developed into an important industry employing 11,000 workers and producing 7,400 tons a year, or about 12% of the world's output. The principal centre is at Besançon, where the Chardonnet process is used (600 tons). Next come the Givet and Izieux works, which use the Despeissis process (500 tons), and finally Argues, which makes artificial silk out of wood pulp (100 tons).

*Paper.*—The French paper industry has always been largely dependent on imports of raw material. Out of 645,000 tons of pulp consumed in 1913, 465,000 tons were imported, and of other raw materials, such as waste paper and rags, there were also large purchases abroad, French paper manufacturers apparently finding it more profitable to import this raw material than to buy in the home market. It must be admitted that France, in spite of her large extent of forest land, is poorly supplied with wood suitable for conversion into pulp. The *epicea*, which is the type of the paper-producing tree, is rare in France. Efforts are being made to substitute *alfa*, of which there are enormous supplies in Algeria and Tunisia, for wood pulp. The use of wild hemp, papyrus, millet stalks, bamboo, rice stalks and baobab, all of which are produced in abundance by France's West African colonies, is still in a very early stage.

*Ceramic Industry.*—The ceramic industry is among those that made the greatest efforts towards development during the World War. It was considerably affected by the invasion, which reduced its output to an extent varying from 25 to 50 per cent. The lack of coal and labour also kept most factories down to about a third of their ordinary capacity; but the war led French manufacturers to use home materials, which they had previously neglected, especially for making tiles and stoneware. Some branches of the industry were greatly stimulated by war needs. For instance, in 1917 61,955 tons of heat-resisting materials were produced (exclusive of crucibles) instead of 350,000 in 1913. Makers also showed a distinct tendency to combination, especially in regard to the use of fuel and the management of ovens. A national ceramic institute was formed, chiefly for developing technical education. The output of crucibles, only 750 tons in 1913, was increased nearly 20 times and considerable impulse was given to graphite mining in Madagascar.

*Dye Industry.*—In France, as in other countries, the dye industry was completely overshadowed by that of Germany. Under pressure of war necessity, three new companies for the manufacture of dyes were founded and the total capital invested in the industry in 1919 was about 80,000,000 fr., but, apart from synthetic indigo and the colours obtainable from sulphur, only a small variety of dyes was produced, and there was a great lack of those required for cotton printing. The needs of the country were so pronounced that the experts who advised the French Government requested the insertion in the Peace Treaty of clauses requiring Germany to supply not more than 5,000 tons of coal by-products and 5,000 tons of dyes every year for 20 years.

*Artificial Perfumes.*—France is fairly well supplied with the artificial perfumes obtained from coal-tar. She has eight factories, some of which are important, producing musk, ionone (essence of violets), terpineol (essence of lilac), vaniline, heliotropine and coumaline, but she was nevertheless a good customer for Germany's synthetic perfumes, as well as for her pharmaceutical products. The discovery and sale of drugs for the cure of human ills has never attracted much attention in France, possibly on account of the innate conservatism of the people and also through the disinclination of French medical men to prescribe new specialties instead of their own combinations of known remedies.

*Glass.*—The principal effect of the war on the glass industry was to encourage the manufacture of retorts, tubes and other laboratory implements, which were previously obtained from Germany, and of optical glass. The output of window-glass has also risen considerably above the pre-war figure. At one time the dumping policy of the Germans and Bohemians enabled them to sell a lamp chimney in Paris for 5 centimes, while the price for the same article in their own countries was 14 centimes. The Germans even succeeded in selling large quantities of bottles, in spite of the fact that France, a great wine-producing country, had thirty or forty modern bottle factories. The liberation of French industry from German competition is especially marked in regard to glass.

*Motor-cars.*—The output of chassis in 1913 was estimated at 45,000, of which only 2,000 were for commercial cars. These chassis were built by 48 firms, employing 53,000 workers, of whom 70% were in the Paris and 11% in the Lyons district. Including the manufacture of radiators, coach work, magnetos, accumulators, tires, etc., the motor-car industry must have employed at least 150,000 workers.

After the war the French motor-car industry chiefly concerned itself with the production of high-class and expensive cars. In spite of an import duty of 45% *ad valorem* and the additional protection, at one time amounting to about 300% in all, given by the depreciation of the franc, very few French makers endeavoured to meet the demand for a moderate-priced car, either in home or foreign markets. As regards the latter, they no doubt felt themselves unable to compete with American makers, and they did not consider the home market sufficiently promising. It was generally estimated that no one living in Paris or any other large French city could keep a private car on less than 100,000 fr. a year, and incomes of this size were very rare in France. The number of cars registered (66,150) in 1919 showed an actual decline on the previous year.

*Chemicals.*—In the 20 years, from 1893 to 1913, the imports of chemicals quadrupled while the exports only tripled, and at the end of the period the difference between exports and imports was about the same as it was at the beginning. The war brought about extraordinary changes in the French chemical industry. France became able to export certain articles, such as cyanide of calcium, chlorides,

chlorates and bromides, of which she previously produced only insignificant quantities. The import of sulphuric acid and ammonia salts ceased and the capacity to export salts of sodium greatly increased. Table 16 shows the estimated production and consumption of chemicals in 1920.

TABLE 16. *Chemical Industry 1920, in tons.*

| | Productive capacity | Consumption |
|---|---|---|
| Carbide of Calcium | 200,000 | |
| Cyanide of Calcium | 300,000 | |
| Ammonia Salts | 200,000 | 150,000 |
| Chloride of Sodium | 1,360,000 | 1,160,000 |
| Salts of Sodium | 800,000 | 650,000 |
| Chlorine (liquid) | 90,000 | 15,000 |
| Bromine | 500 | 200 |
| Commercial Sulphuric Acid | 2,250,000 | 1,500,000 |

France is poorly supplied with the raw materials of the chemical industry except as regards salt. In 1914 only one mine of pyrites (on which the production of sulphuric acid largely depends) was being worked. It produced 293,000 tons in 1913. During the war work was resumed in two previously abandoned mines, but the result was insignificant, and the French industry remained dependent on imported pyrites, chiefly from Spain, where about 75% of the production is controlled by British and 15% by French companies.

The restoration of Alsace should render France independent as regards potash. The Alsatian deposits, which are between the Vosges and the Rhine, extending from near Mulhouse to beyond Colmar, consist of two superimposed layers, the lower being much the larger. Its area is 120 sq. m., and it is estimated to contain 1,472,000,000 tons of crude potash richer in quality than the German deposits. Under German rule the annual output of the Alsatian potash-mines was limited to 5% of the German production, and in 1913 was 50,000 tons, or slightly more than the whole French consumption then.

Before the war France ranked sixth among the salt-producing countries. The eastern departments, such as Meurthe-et-Moselle, Haute-Saône, Doubs and Jura, supplied 856,000 tons of rock-salt in 1913, and the southwest (Landes, Basses-Pyrénées and Haute-Garonne) 43,000 tons. The evaporation of sea-water gave 382,500 tons. These resources are now increased by about 80,000 tons, from Alsace-Lorraine.

*Radium.*—France, where radium was first experimented with and discovered by M. and Mme. Curie in 1898, has no known deposits of suitable ore. Before the war there were three French factories, at Nogent, St. Denis and Gif, and their total output in 1913 was 435 centigrammes, the gramme being then worth £30,000. A fourth plant for the treatment of radium-bearing ores was established during the war, but much greater progress was made in the United States and England, and, in view of the cost of importing ore, it is questionable whether the production of radium can be remunerative in France.

*Aviation.*—The position of the French industry at the outbreak of war is shown by Table 17.

TABLE 17. *Aviation Manufacturing Firms, 1914.*

| | Paris District | Other Districts |
|---|---|---|
| Motors | 22 | 1 |
| Aeroplanes | 27 | 7 |
| Seaplanes | 13 | 5 |
| Airships | 7 | 0 |
| Propellers | 6 | 0 |
| Hangars | 5 | 1 |
| Totals | 80 | 14 |

The industry was to a large extent concentrated in Paris, but most of the factories were small and worked independently, so that they were very imperfectly prepared for the demands of the army. The French makers nevertheless succeeded not only in producing constantly varying types of military machines for their own country but were able to export to the Allies. England bought 59 French machines in 1915, but was afterwards independent. In this year the French exports totalled 22,427,000 fr., but subsequently decreased as the Allies built up their own aeroplane industries for war purposes. An instance of this development is the fact that in 1918 Italy supplied France with 1,762 motors, against 3 in 1917. It was thus evident, long before the close of hostilities, that the countries which had been France's allies in war would be her rivals in the peace-time developments of the aeronautical industry.

*Economic Prospects in 1921.*—The spirit in which the economic leaders of France proposed to deal with the extremely difficult situation remaining after the war was shown in the conclusions of the monumental report drawn up by a committee of experts under the presidency of M. Clementel, Minister of Commerce, and published at the end of 1919. France, it is there pointed out, must both reconstitute and develop. She must live as much as possible on her own resources so as not to add to her foreign debt. She must increase exports so as to reduce it.

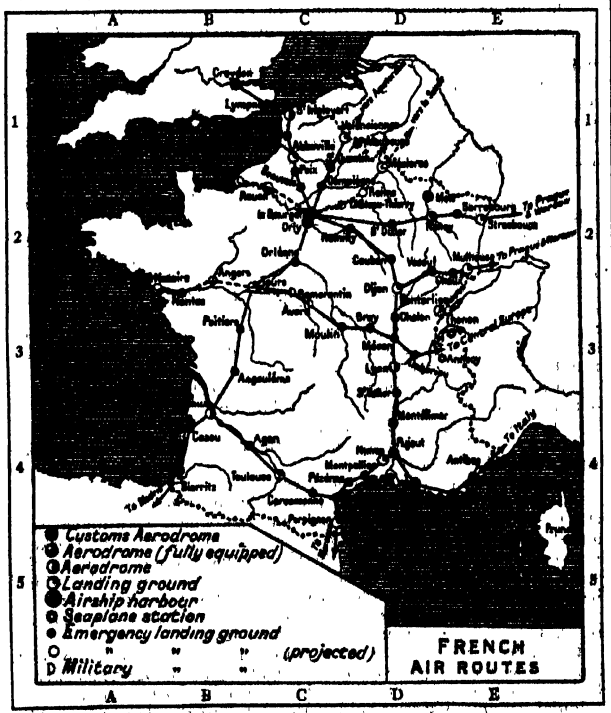
"This plan," the report continues, "can be achieved. The France of to-morrow will have 30% of the world's supply of iron ore and will rank second in the list of producing countries, immediately after the United States. This iron ore can be exchanged for the raw materials which France requires. But there is something more to be done. France can no longer rest content with exporting her natural wealth. She must compete in the foreign markets of manufactured goods and export machinery as well as ore. The effort to produce must apply to all industries engaged in the transformation of raw materials. Only in this way can we return to a healthy condition of foreign exchange and shake off a crushing burden of debt.

"It is not enough, however, to produce, even at advantageous prices. We must sell. We must find customers, and keep them, and this last result can only be attained if we take a lesson from the results achieved by Germany and make up our minds to modern methods, which means that we must study markets so as to find out what is wanted and then adapt our manufactures to the demand. We must cease to try to make foreign buyers accept our ideas as to what goods are best, and we must make our manufactures conform to the ideas of buyers. Furthermore the French banks must adapt themselves to the system of long credits, to which German competition owed its development in foreign markets.

"A revision of our customs tariffs has become indispensable. Our import duties should be reduced as far as possible, so as not to constitute a premium on lack of enterprise and so as not to expose our export trade to reprisals. Though France now holds the second rank among the countries of the world for iron ore, she has not enough coal to transform this ore into iron and steel. Her wealth would be useless to her if a customs barrier stood between her and those who supply her with coal. What is true of coal is equally true of other raw materials, and we must thus come to the conclusion that the theory of compensating tariffs is out of date and that our legislation must be on a wider basis."

After thus defining the essential principles to be followed in regard to national economic progress, the report draws attention to certain internal obstacles, such as lack of labour, the low birth-rate, the spread of tuberculosis and syphilis, the drink traffic, insanitary housing and other conditions contrary to economic and industrial development. According to an estimate by M. March, Directeur de la Statistique Générale, if the population of France had gone on increasing at the average rate until 1935, the country would then have had 12,300,000 males between 16 and 65 years of age, but, after allowing for the numbers of men killed in the war (1,400,000) and the consequent deficit in male births between 1914 and 1919, the figure for 1935 cannot be put at more than 10,300,000. It must also be remembered that among the male survivors of the war there were 350,000 who were totally disabled as regards military service, 450,000 who were partially disabled, and an unknown number of men who sustained less serious injuries. These figures indicate a lessening of the available supplies of labour over and above the decrease caused by actual loss of life.

The ravages of tuberculosis in France are shown by the fact that, while the increase in population for the years 1909, 1910, 1912 and 1913 was 15,000, 71,000, 58,000 and 42,000, respectively, the deaths from tuberculosis in those years were 85,085, 84,956, 83,727 and 84,443. In 1912 the number of deaths from tuberculosis was 38,083 in England and 85,976 in Germany. In the same year the rates of mortality from this disease were 1·76 per thousand inhabitants in France, 1·30 in Germany, 1·04 in England and 0·93 in Belgium.



The drink danger to France is summed up in figures supplied by the *Statistique Générale* and the *Ligue Nationale contre l'Alcoolisme*. It gives the quantity of distilled alcoholic liquor (expressed in litres of proof spirit per head of population) as 5·02 in France, 3·23 in Belgium, 3·10 in Russia before the war, 2·84 in the United States, 2·8 in Germany, 1·88 in Switzerland, 1·82 in Norway, 1·74 in the United Kingdom, and 0·67 in Italy.

The conversion of war-time equipment to the requirements of peace was one of the principal problems of French industry in 1920–1. Aeroplane motor makers were now turning out machine tools, of which 48,000,000 francs' worth was imported in 1913, this quantity being nearly five times as much as the home output. Half of these imports came from Germany. Machinery used for making shells and small arms has been adapted to the

manufacture of certain portions of textile machinery, sewing-machines (of which 3,633 tons came from Germany in the last year before the war) and typewriters. Some constructors of tanks have turned their attention to agricultural machinery. The practical results of these adaptations, and their capacity to withstand foreign competition, cannot of course be known until after the restoration of something like normal conditions.

The conditions necessary for obtaining the best results from French industry after the war are thus set forth by M. Rateau in his report to the Consulting Committee on Arts and Manufactures:—

(1) The formation of manufacturers' syndicates should be developed as much as possible, and manufacturers themselves should be asked to abandon their present individual policy. The question whether syndicates should not be made compulsory should be examined and discussed.
(2) The State should be asked to give more active coöperation to industry and keep in closer and more permanent touch with it, while at the same time leaving full scope to private initiative.
(3) Factories and workshops should be specialized.
(4) The standardizing of machinery should be very thoroughly investigated.
(5) Manufactures should be concentrated in the smallest possible number of factories.
(6) There should be scientific control of manufactures.
(7) Special and general laboratories, which are indispensable to industry, should be created.
(8) Inventions should be protected by utilizing them better.
(9) Technical education of all kinds should be developed.
(10) A system of technical evening schools should be built up.

*Aerial Route Map* (see *p. 119*).

## Communications

*Railways.*—France has never been well provided with railway communication. When the war of 1870 broke out, the total length of her railway systems was only 9,658 miles. M. de Freycinet's development scheme was the cause of more rapid progress between 1875 and 1890, after which date the rate of extension slackened. In 1912 the total length of main and branch lines was 31,600 miles. This gave France the third place among European countries as regards the length of her railway system, but in proportion to population and geographical area only the sixth and eighth places respectively.

This deficiency in the national equipment was a serious handicap during the greater part of the World War, not only as regards military operations but the conveyance of the vast quantities of supplies. The ports on the Channel and Atlantic immediately became congested, and one of the most urgent tasks of the French engineers was to lay many miles of sidings and create sorting stations. In all about 620 m. of new track were laid in France during the war. Some of the French railways accomplished something like miracles in the face of enormous difficulties. The Northern railway was suddenly called upon, in March 1918, to provide 172 troop trains a day after having for some time run only 18 of these trains a day. The military train mileage which was 621,000 in Feb. doubled in May, although Amiens was under the enemy's fire. On the Eastern line, the daily number of troop trains reached 198 on May 5. The effort was continued after the onrush of the enemy had been stopped and the forward movement of the Allied troops begun. On Aug. 28 1918, the Northern line was running 25,000 waggons of all kinds, chiefly over tracks which had been torn up by the enemy and hastily relaid. After the Armistice, the conveyance of troops and prisoners required the French railways to provide 206 trains, 10,156 vans and trucks, 550 passenger carriages and 750 engines. The damage done to the Northern railway alone comprised 500 bridges and culverts, 12 tunnels, nearly 2,000 m. of telegraph and telephone lines, 590 buildings, 150 water-tanks and 20,000 tons of metal work.

On Jan. 1 1919, the rolling-stock on the French railways was: locomotives 14,574, goods trucks 368,683, passenger carriages and vans 43,956. The corresponding figures on Aug. 1 1914 were: locomotives 13,800, goods trucks 376,000, passenger carriages and vans 49,320. On the other hand, 2,854 locomotives and 46,337 trucks and carriages were out of use on Jan. 1 1919, as compared with 1,720 locomotives and 19,314 trucks and carriages on Aug. 1 1914.

Under the terms of the Armistice, France obtained 2,600 locomotives and 70,000 trucks and carriages from Germany, so that she entered upon the peace period with apparently a large increase in her railway rolling-stock, but much of it was more or less useless, the scarcity of skilled labour during the war having prevented proper repairs.

France in 1913 had six engineering works producing railway locomotives. Four of the six were in districts subsequently occupied by the enemy. The total output was between 650 and 700 engines a year. The other rolling-stock manufactured in France was about 2,000 passenger carriages and 18,000 goods trucks a year. During the last few years preceding the war, from one-third to one-sixth of the new engines required by the French railways were imported from abroad, the exports being almost entirely confined to Belgium and the French colonies. Since the war, new workshops have been built, one of which at Nantes has a capacity of 200 locomotives a year. It was estimated that in a few years France would be in a position to meet all her own requirements in railway rolling-stock, and possibly to export it, on condition that the placing of orders by the companies was carried out with more regularity than in the past.

Improvement in railway communications with other countries is greatly needed. The only two routes between France and Italy, via Modane and Ventimiglia, are overcharged with traffic. The Modane line through the Alps is liable to interruption by floods. Some progress has, however, been made with a new line between Nice and Coni (Cuneo), which will serve the Milan district. Between France and Spain there are two lines, via Hendaye and Cerbère. Two others have been begun, from Ax-les-Thermes to Ripoll and from Oloron to Quera. Many other extensions are held up through financial and other causes. Public opinion appears to be strongly in favour of the Channel-tunnel scheme.

Little has been done in France towards the electrification of railways. With the exception of the Paris–Versailles line on the left bank of the Seine, and the Orléans line between Paris and Juvisy, the only French railway company to use electric traction is the Midi, which can obtain power comparatively cheaply from the Pyrénéan waterfalls. This company has planned to electrify 170 m. of its system, but the work is not completed. Before the war, the State railway had made arrangements to electrify all its Paris suburban lines, and part of the work was carried out. It was resumed in 1920, and, it is estimated, will be finished in 1926.

One of the weakest points in the system of communications is to be found at Havre. This important port is not only imperfectly connected with other towns in its own region but only one railway line links it with the largest and most active centre it has to serve —Paris. Rouen is better off than Havre in this respect, as it stands on both banks of the Seine and, for the conveyance of goods at any rate, can make use of river transport, but many of its industrial districts, and parts of its port, are badly served by rail in the direction of Paris. The building of a new line from Havre, connecting with the Paris main line at Pont de L'Arche and thus relieving the pressure on the route through the Rouen bottle-neck, has been advocated for many years, but up to the summer of 1921 its execution had not been undertaken. A petroleum pipe-line between Havre and Paris was, however, in course of construction.

Another project under consideration was designed to improve communications between Switzerland and the Atlantic coast, so as to attract traffic which would otherwise continue to follow the Hamburg, Rotterdam and Antwerp routes. Before the war, Berne was 15 hours from Antwerp, 16½ hours from Hamburg and 21 hours from Bordeaux. The problem from the French point of view is how best to reduce the time of transit between Berne and Bordeaux. The nature of the French lines (as they existed in 1921) does not permit of trains being run at greater speed. The central French mountain mass, which stands directly on the line between these two points,

prevents the construction of tracks with small gradients and wide curves. The best solution of the problem is to be found in a new line, 115 m. long, connecting the Orléans system, near Limoges, with the P.-L.-M. railway near St. Germain-des-Fossés. This would shorten the journey between Bordeaux and Lyons by over three hours, but financial considerations have been adverse.

*Shipping.*—France, in 1914, had seven shipbuilding yards with the following number of drydocks from 300 to 600 ft. long: Chantiers de France 5, Chantiers de St. Nazaire et Penhoët 4, Chantiers de Normandie 5, Chantiers de la Loire 7, Chantiers de la Gironde 4, Chantiers de Provence 6, Forges et Chantiers de la Méditerranée (La Seyne and Havre) 11. Other shipyards of smaller dimensions were: Chantiers Normand 3, Delaunay-Belleville 2, Chantiers Dubigeon 2, Chantiers de Bretagne 4, Dyle et Bacalan 3, Société Provençale 2, Barriel 4. There were also yards at St. Malo, Paimpol, etc., for the construction of wooden vessels. The output of these yards before the war is shown in Table 18, based on Bureau Veritas figures.

TABLE 18. *Shipbuilding Output.*

| | Steamers | | Sailing Vessels | |
|---|---|---|---|---|
| | No. | Tonnage | No. | Tonnage |
| 1912 | 41 | 124,665 | 66 | 9,000 |
| 1913 | 31 | 105,820 | 35 | 6,068 |
| 1914 | 22 | 93,830 | 18 | 2,353 |

The figures for vessels purchased abroad in 1912–4 are shown in Table 19.

TABLE 19. *Steamers Purchased Abroad.*

| | Steamers | | Sailing Vessels | |
|---|---|---|---|---|
| | No. | Tonnage | No. | Tonnage |
| 1912 | 62 | 96,858 | 10 | 2,203 |
| 1913 | 77 | 79,379 | 5 | 1,294 |
| 1914 | 17 | 30,416 | 3 | 1,717 |

In spite of foreign purchases, the French merchant fleet did not increase in proportion to those of other countries. It amounted, in 1914, to 2,498,286 tons. This was reduced, by war and other losses, to 1,932,862 tons at the end of 1917, despite the addition of 301,000 tons of vessels built or purchased abroad. At the conclusion of hostilities, the French tonnage was further reduced to 1,448,242 tons, against which should be set another 400,000 tons of vessels built or purchased abroad. In round figures, the actual loss of tonnage during the war was 1,000,000. Moreover, many vessels afloat were practically useless owing to lack of repair. Shipbuilding during the war amounted to only 150,000 tons, and as the capacity of the French yards was estimated at 140,000 tons a year, the net deficit in new ships, as the result of 4½ years of war, was 630,000 tons —150,000 = 480,000. This, added to the actual loss, represents a deficit of about a million and a half tons of shipping due to war.

After the war France had five new shipbuilding concerns with from six to eight drydocks and able to build ships of from 3,000 to 8,000 tons. These companies and their capital (including both shares and debentures) were as follows:—Chantiers Navals Français 60,000,000 fr., Atéliers et Chantiers de la Seine Maritime 30,000,000 fr., Compagnie Générale de Constructions Navales 35,000,000 fr., Société Normande de Constructions Navales 25,000,000 fr., Chantiers Généraux de Cette 45,000,000 francs.

The progress made in the restoration of the French mercantile marine after the war is shown by figures published in the *Annuaire du Comité des Armateurs de France.* They give 1,886,919 as the gross tonnage on Jan. 1 1919, and 2,076,963 at the end of that year. Six months later (June 30 1920) the gross tonnage had risen to 2,180,345. If we include the *flotte d'état* (vessels worked by the State during the war and intended for gradual transfer to French ship-owners) we find that 19 months after the close of hostilities, the French merchant fleet was nominally stronger than it was before the war, inasmuch as the *flotte d'état* amounted to 452,943 tons, in addition to 150,000 tons of former enemy ships temporarily handed over to purchasers. The *flotte d'état*, however, was an acquisition of doubtful value, many of the ships having been purchased only under the pressure of war necessities. As regards quality of material, the French mercantile marine in 1921 was certainly below the 1914 standard, and its working was heavily handicapped by the eight-hour day.

The post-war mercantile shipbuilding programme, based on ship-owners' requirements and the gradually increasing capacity of the yards, old and new, is shown in Table 20.

TABLE 20. *Shipbuilding Programme 1919–23.*

| Year | Number of Ships | Gross Tonnage |
|---|---|---|
| 1919 | 86 | 374,344 |
| 1920 | 159 | 605,665 |
| 1921 | 172 | 704,361 |
| 1922 | 176 | 765,377 |
| 1923 | 184 | 793,405 |

The completion of this programme depended on a considerable reduction in naval shipbuilding, a sufficient supply of steel and other materials and of skilled labour and the ability of the yards to carry out their contracts.

*Wireless Telegraphy.*—As soon as the practicability of communication by wireless telegraphy was demonstrated, the French Government took steps to utilize the new process, but at first only for military and naval purposes. A military station was established at the Eiffel Tower, in Paris, under the control of the War Ministry. The navy had two stations, one at Ushant, on the north-west coast, and the other on Porquerolles I. on the coast of Provence. Up to the time of the World War, however, the transmission and reception of messages was uncertain, the instruments then in use not being adaptable with sufficient exactitude to varying wave lengths. Considerable technical progress was made during the war. To assist the Eiffel Tower in the work of maintaining communication with Allied armies operating away from the French front, the War Ministry built a new station at La Doua, near Lyons, and the Ministry of Marine erected, at Basse-Lande, near Nantes, a very powerful station which enabled it to keep in touch with French naval forces in distant seas. These three stations also sent out propaganda messages, and smaller stations along the coasts kept up communication with Allied vessels in the Atlantic, the Channel and the Mediterranean. While the war was still in progress, the U.S. military authorities began the construction, at Croix d'Hins, near Bordeaux, of a new station which was to be reserved for messages between the American army headquarters and Washington. This station was not completed until after the close of hostilities. It was eventually able to transmit messages, under favourable conditions, to distances of about 7,000 m., and to communicate with the United States, Japan, Madagascar and the French colonies generally. This station, at the time the most powerful in the world, was handed over to the French War Department on Nov. 15 1920, and was formally presented to the French Government by Admiral Magruder, on behalf of the U.S. Government, about a month later.

The use of wireless telegraphy for civilian purposes in France may be said to date back to 1904, in which year the Post Office took over the naval stations at Ushant and Porquerolles, through which private messages to and from ships at sea were then transmitted. This service has been considerably developed, and in June 1921 nine stations were open in connexion with it—at Boulogne-sur-Mer, Havre, Ushant, La Bouscat (Bordeaux), Saintes-Marles de la Mer, Marseille, Cros de Cagnes (Nice), Bonifacio and Fort de l'Eau (Algiers). Other stations, such as Dunkirk, Dieppe, Cherbourg, Lorient and 'Ain el Turk (Oran) were also available to the public. Short-range stations were being established in mountainous districts so as to enable communication to be maintained in case of interference with the ordinary telegraphic circuits by snowfalls or other causes. There was also wireless communication between France and the principal islands on the coast. Messages to places abroad were sent from four stations—La Doua (Lyons), Croix d'Hins (Bordeaux), Basse-Lande (Nantes) and the Eiffel Tower and there were receiving stations at Villejuif, near Paris, Poitiers, Neuchâtel, Chartres, Basse-Lande and the Eiffel Tower. Communication by wireless had been established with the following countries:—

Europe:—Great Britain, Hungary, Yugoslavia, Bulgaria, Rumania, Norway, Austria, Poland and Turkey.

Asia:—China and Indo-China.

Africa:—French Colonies in northern, western and equatorial Africa and Madagascar.

America:—United States and West Indies.

All the stations available to the public are under the control of the Post Office, but the two great stations which were under construction in 1921 at Sainte Assise, near Melun, were to be worked, under Post-Office control, by the Compagnie Radio-France, an offshoot of the Compagnie Générale de Telegraphie Sans Fil, which had stations in various parts of the world. The rates, which are not yet definitely fixed, are generally about the same as those charged by cable companies but in some cases are less.

In addition to the two very powerful and modern stations at Sainte Assise, the French authorities had begun in 1921 to construct transmitting stations which would eventually form a great intercolonial system. Those at Saida (Algeria), Bamako (Upper Senegal), Brazzaville (Congo), Antananarivo (Madagascar) and Saigon (Indo-China) were to be completed in the summer of 1921. Others were to be established at Jibuti, Numea, Tahiti and Cayenne (Guiana).

*Aerial Navigation.*—Before the war the length of air journeys seldom exceeded 250 m. and very little extra weight could be carried. It did not seem likely that aviation could serve any real commercial purpose, at any rate for several years to come. The technical progress made under pressure of war necessities was, however, so great that every country which had taken part in the hostilities, and, through the force of circumstances, found itself in possession of a well-developed aviation industry, set to work to make the best use of it in the service of peaceful enterprise, especially as this new industry would be indispensable to military operations.

In 1919 French civilian aviation, then at its beginning, was controlled merely by a department of the War Office. This department soon developed into what was called the "Organe de coördination générale de l'aéronautique" under which the various scattered aviation services were placed. Aviation first obtained its autonomy by the creation, in Jan. 1920, of a separate Under-Secretaryship of

State, for the control and development of air transport. The meteorological services previously connected with five different ministries were placed under the new department.

It was apparent from the outset that commercial aviation could be neither a purely private nor a purely State enterprise. If the State held aloof, the great initial expense would check development and keep down competition, so that when a service was established, there would be a tendency, in the absence of competition, to take advantage of the situation and exploit the public. If, on the other hand, the State accepted a monopoly of the enterprise, the result would be to create an artificial atmosphere unfavourable to development. Nevertheless, the State necessarily had to exercise some sort of control. The new means of transport called for a discipline similar to that of the mercantile marine. There were certain international obligations which could not be carried out in the absence of regulations enforced by law. There could be no general system of air navigation without air ports, landing grounds, repair and supply stations. All these formed part of a foundation which only the State could direct and maintain. The companies who contemplated embarking upon the business had few suitable machines, and the public had to be gradually educated to the utility of the new service. It was evident that the industry must have State support.

From the first it appeared that the main lines of communication would be as follows (*see* Map, p. 117):—

London, Calais, Paris, Dijon, Lyons, Marseilles, Italy, and the East.

Amsterdam, Brussels, Valenciennes, Paris, Bordeaux, Bayonne, and Spain.

Havre, Paris, Strassburg, Central Europe and the East.

Bordeaux, Toulouse, Marseilles, Italy and the East.

Casablanca, Oran, Algiers and Tunis.

At the end of 1919, very little had been done towards the work of providing these routes with landing and supply stations, repair shops, wireless and weather services. The Government had only four stations: at Le Bourget, near Paris; Bordeaux; Avignon, and Lille. Repairs could be effected only at Le Bourget and Bordeaux. There was no weather service, and communication by wireless between the various lines was uncertain.

At the end of 1920 considerable progress had been made. Thirteen air ports, stations or landing-places had been fitted up, there were seven emergency landing-places and negotiations were in progress for the purchase of land for 28 others. Some had nothing but a caretaker and a telephone; others had appliances for temporary repairs, and others again had regular workshops. Some were provided with corrugated iron shelters about 100 ft. square. The process of marking out the routes had begun. Seven lighthouses, each visible at 25 m., were in use. Another, with a range of 90 m., was being built in the summer of 1921 with a view to flights across the Mediterranean. There were 10 wireless stations giving communication between the terminal stations of the Paris-London, Paris-Brussels, and Paris-Strassburg lines. The aerodromes at Le Bourget and Saint Inglevert, on the Paris-London route, were also provided with wireless telephone apparatus for communication with the pilots of machines in the air. The meteorological system included 20 stations, divided into three groups covering the whole country. These stations sent out weather reports four times a day and also recorded observations of great use to air navigators.

In 1919, despite the uncertainty of the situation and the almost complete absence of organization, four French companies, with the help of State subsidies, were carrying on regular air transport.

There was considerable development in 1920 as regards the number of new enterprises and the additional lines, both national and international, opened to traffic.

On the purely French system, the Nîmes-Nice line, worked for nine months in 1920, carried 25 passengers and 215 kgm. of parcels. The Paris-Cabourg line in five weeks carried 44 passengers and 882 kilogrammes. The results for the first four months of 1921 showed still further progress.

Flying had become sufficiently well established in France in the summer of 1921 to justify the publication of a monthly time-table. It may be of interest to summarize the information given therein as to the various services in operation in France:—

Bordeaux-Toulouse-Montpellier line. Daily, except Sundays and holidays. Time, Bordeaux to Toulouse, 1¾ hours; Toulouse to Montpellier, 1¼ hours. Fares: Bordeaux-Toulouse, 88 fr.; Toulouse-Montpellier 88 francs. Goods, 3 fr. 30 centimes per kilogramme.

Nîmes-Nice line. Mondays and Thursdays. Time, 2 hours 50 minutes. Fare, 240 fr. Goods, 4 fr. 50 centimes per kilogramme. Connexion at Avignon with express trains on P.-L.-M. main line.

Toulouse-Spain-Morocco line. Toulouse-Barcelona. Tuesdays, Wednesdays, Fridays and Sundays. Time 2½ hours. Fare, single 468 fr., return 795 francs. Toulouse-Alicante-Malaga-Rabat-Casablanca. Mondays, Wednesdays, Thursdays and Saturdays. Fares from Toulouse to Alicante 924 fr., to Malaga 1,068 fr., to Rabat 1,360 fr., to Casablanca 1,680 fr. Goods Toulouse to Rabat 9 fr. per kgm., Casablanca 10 francs.

Paris-London, daily, except Sunday. Worked by four companies. Time, from 2½ hours to 3 hours. Fares, single 300 francs. Goods, 1 fr. 50 centimes per kgm. up to 6 kgm., 6 fr. from 6 to 25 kgm., 5 fr. above 25 kilogrammes.

Paris-Brussels-Amsterdam line. Daily to Brussels and Rotterdam; Tuesdays, Thursdays and Saturdays to Amsterdam. Fares, Brussels 175 fr., return 300 fr.; Amsterdam 300 fr., return 500 francs. Goods, from 2 fr. 50 centimes to 6 fr. 50 centimes according to weight and distance.

Paris-Strassburg-Prague-Warsaw. Paris to Strassburg, Tuesdays, Thursdays and Saturdays. Strassburg to Prague and Warsaw, Mondays, Wednesdays and Fridays. Fares, Strassburg 150 fr., Prague 500 fr., Warsaw 800 francs. Goods from 2 fr. to 6 fr. 50 centimes per kilogramme.

Bayonne-Bilbao-Santander line. To Bilbao daily, except Sundays. To Santander, Mondays only. Fares, Bilbao 100 fr., Santander 150 francs. Goods, from 75 centimes to 1 fr. 50 centimes per plate kilogramme.

*Rivers.*—France's river traffic in normal times is considerable (42,000,000 tons a year). Practically the whole is carried in ordinary barges, the costs of vessels with auxiliary engines having been found too great to compete with the older styled transport. A few cement barges were built during the war, in consequence of the shortage of plates, but as one of these vessels weighs about 220 tons more than a steel barge of the same length (150 ft.), the cost of traction is prohibitive. (C. A.)

*The Rhine.*—The traffic on the Rhine is controlled by a system of treaties which dates back to 1804. Before that date the many riverain states used their position to levy toll upon river traffic; only boatmen of specified states were allowed to carry on their trade within certain sections of the river. The appearance of the Republican armies on the Rhine naturally put an end to this archaic system of complicated restricted monopoly. In 1804 Napoleon and the German representative signed the First Convention of the Rhine, in which the principle of free navigation and the suppression of tolls was laid down. This Convention has had many successors. When the Treaty of Versailles was signed the Mannheim Convention of Oct. 17 1868 was still in force. This instrument maintained the freedom of international navigation and the suppression of all traffic taxes. The International Control Commission of the Rhine was entrusted with the duty of enforcing its stipulations. It was formed by commissioners, appointed by Holland, Prussia, Hesse, Bavaria, Baden and France. The Treaty of Frankfurt shut France off from the Rhine. After 1871, Germany sought more and more to make her authority predominant in the Control Commission, and only to apply those clauses of the Convention which accorded with German interests. Thus in 1911 an imperial law created navigation taxes on German rivers, but the empire at that time had not the courage to ignore the protests of the other states, and to apply this law to the treaty rivers of the Rhine and the Elbe. During the war, in 1917, however, a transport tax was applied to Rhine traffic, in defiance of the Mannheim Convention, and in spite of the protests of Holland, the only non-German state represented on the Commission. When Marshal Foch, commander-in-chief of the Allied armies, came to the Rhine in 1918, like Napoleon, these fetters were again broken. The question of admitting Switzerland to the Commission had been raised in Berlin in 1903, when the Prussian Minister of Public Works declared: "The admission of Switzerland is not to be desired. We have already seen what the admission of Holland has cost us. To-day Switzerland, a riverain state of the Rhine, has been admitted, and the Treaty of Versailles lays down that the Control Commission of the Rhine provided for by the Mannheim Convention, shall consist of 19 members, two representatives each of Holland, Switzerland, Great Britain, Italy and Belgium, four representatives of the German river-side states, four of France, who is given the right to nominate the president of the Commission. The seat of this new Commission is in the old palace of the German Emperor, which was built at Strassburg in 1888, and is now known as the Rhine Palace. Article 354 of the Versailles treaty charges the Control Commission with the task of revising the Mannheim Convention, which was being done in 1921 under M. Claveille.

France, by reason of Art. 358 of the Versailles treaty, has the right to take Rhine water for canals already in existence or still to be built. The same clause gives her exclusive rights in the energy produced by river improvement, provided that she pay to Germany half the value of the energy so produced. It is proposed to build a Grand Canal d'Alsace which, running alongside the Rhine from Huningue (Hüningen) north of Basle, will join the river again near Strassburg. This canal will improve navigation, and produce hydraulic power. At Strassburg the fall in the Rhine amounts to as much as 60 cm. per kilometre. From Brisach to Basle it varies between 90 cm. and 1·02 metres per kilometre. The Rhine is a wild and capricious river, especially between Basle and Strassburg. The stream has been tamed between Strassburg and Lauterburg, where the fall is only 44 cm. per km., but between Basle and Strassburg this has not been possible. The river is constantly making its own bed deeper. But in front of Istein the digging-down process has reached a projecting rocky bottom, and in ten years' time a cataract will have been formed there which will make all navigation impossible. The system of controlling the waters, which has been successfully used between Strassburg and Lauterburg, is not applicable to the Strassburg-Basle reach. Moreover, with high water much more than only two metres of water on this latter stretch, and traffic is impossible during three months of the year. Also, so strong is the current that

prevents the construction of tracks with small gradients and wide curves. The best solution of the problem is to be found in a new line, 115 m. long, connecting the Orléans system, near Limoges, with the P.-L.-M. railway near St. Germain-des-Fossés. This would shorten the journey between Bordeaux and Lyons by over three hours, but financial considerations have been adverse.

*Shipping.*—France, in 1914, had seven shipbuilding yards with the following number of drydocks from 300 to 600 ft. long: Chantiers de France 5, Chantiers de St. Nazaire et Penhoët 4, Chantiers de Normandie 5, Chantiers de la Loire 7, Chantiers de la Gironde 4, Chantiers de Provence 6, Forges et Chantiers de la Méditerranée (La Seyne and Havre) 11. Other shipyards of smaller dimensions were: Chantiers Normand 3, Delaunay-Belleville 2, Chantiers Dubigeon 2, Chantiers de Bretagne 4, Dyle et Bacalan 3, Société Provençale 2, Barriel 4. There were also yards at St. Malo, Paimpol, etc., for the construction of wooden vessels. The output of these yards before the war is shown in Table 18, based on Bureau Veritas figures.

TABLE 18. *Shipbuilding Output.*

| | Steamers | | Sailing Vessels | |
|---|---|---|---|---|
| | No. | Tonnage | No. | Tonnage |
| 1912 | 41 | 124,665 | 66 | 9,000 |
| 1913 | 31 | 105,820 | 35 | 6,068 |
| 1914 | 22 | 93,830 | 18 | 2,353 |

The figures for vessels purchased abroad in 1912–4 are shown in Table 19.

TABLE 19. *Steamers Purchased Abroad.*

| | Steamers | | Sailing Vessels | |
|---|---|---|---|---|
| | No. | Tonnage | No. | Tonnage |
| 1912 | 62 | 96,858 | 10 | 2,203 |
| 1913 | 77 | 79,379 | 5 | 1,294 |
| 1914 | 17 | 30,416 | 3 | 1,717 |

In spite of foreign purchases, the French merchant fleet did not increase in proportion to those of other countries. It amounted, in 1914, to 2,498,286 tons. This was reduced, by war and other losses, to 1,932,862 tons at the end of 1917, despite the addition of 301,000 tons of vessels built or purchased abroad. At the conclusion of hostilities, the French tonnage was further reduced to 1,448,242 tons, against which should be set another 400,000 tons of vessels built or purchased abroad. In round figures, the actual loss of tonnage during the war was 1,000,000. Moreover, many vessels afloat were practically useless owing to lack of repair. Shipbuilding during the war amounted to only 150,000 tons, and as the capacity of the French yards was estimated at 140,000 tons a year, the net deficit in new ships, as the result of 4½ years of war, was 630,000 tons —150,000 = 480,000. This, added to the actual loss, represents a deficit of about a million and a half tons of shipping due to war.

After the war France had five new shipbuilding concerns with from six to eight drydocks and able to build ships of from 3,000 to 8,000 tons. These companies and their capital (including both shares and debentures) were as follows:—Chantiers Navals Français 60,000,000 fr., Atéliers et Chantiers de la Seine Maritime 30,000,000 fr., Compagnie Générale de Constructions Navales 35,000,000 fr., Société Normande de Constructions Navales 25,000,000 fr., Chantiers Généraux de Cette 45,000,000 francs.

The progress made in the restoration of the French mercantile marine after the war is shown by figures published in the *Annuaire du Comité des Armateurs de France.* They give 1,886,919 as the gross tonnage on Jan. 1 1919, and 2,076,963 at the end of that year. Six months later (June 30 1920) the gross tonnage had risen to 2,180,345. If we include the *flotte d'état* (vessels worked by the State during the war and intended for gradual transfer to French ship-owners) we find that 19 months after the close of hostilities, the French merchant fleet was nominally stronger than it was before the war, inasmuch as the *flotte d'état* amounted to 452,943 tons, in addition to 150,000 tons of former enemy ships temporarily handed over to purchasers. The *flotte d'état*, however, was an acquisition of doubtful value, many of the ships having been purchased only under the pressure of war necessities. As regards quality of material, the French mercantile marine in 1921 was certainly below the 1914 standard, and its working was heavily handicapped by the eight-hour day.

The post-war mercantile shipbuilding programme, based on ship-owners' requirements and the gradually increasing capacity of the yards, old and new, is shown in Table 20.

TABLE 20. *Shipbuilding Programme 1919–23.*

| Year | Number of Ships | Gross Tonnage |
|---|---|---|
| 1919 | 86 | 374,344 |
| 1920 | 159 | 605,665 |
| 1921 | 172 | 704,361 |
| 1922 | 176 | 765,377 |
| 1923 | 184 | 793,405 |

The completion of this programme depended on a considerable reduction in naval shipbuilding, a sufficient supply of steel and other materials and of skilled labour and the ability of the yards to carry out their contracts.

*Wireless Telegraphy.*—As soon as the practicability of communication by wireless telegraphy was demonstrated, the French Government took steps to utilize the new process, but at first only for military and naval purposes. A military station was established at the Eiffel Tower, in Paris, under the control of the War Ministry. The navy had two stations, one at Ushant, on the north-west coast, and the other on Porquerolles I. on the coast of Provence. Up to the time of the World War, however, the transmission and reception of messages was uncertain, the instruments then in use not being adaptable with sufficient exactitude to varying wave lengths. Considerable technical progress was made during the war. To assist the Eiffel Tower in the work of maintaining communication with Allied armies operating away from the French front, the War Ministry built a new station at La Doua, near Lyons, and the Ministry of Marine erected, at Basse-Lande, near Nantes, a very powerful station which enabled it to keep in touch with French naval forces in distant seas. These three stations also sent out propaganda messages, and smaller stations along the coasts kept up communication with Allied vessels in the Atlantic, the Channel and the Mediterranean. While the war was still in progress, the U.S. military authorities began the construction, at Croix d'Hins, near Bordeaux, of a new station which was to be reserved for messages between the American army headquarters and Washington. This station was not completed until after the close of hostilities. It was eventually able to transmit messages, under favourable conditions, to distances of about 7,000 m., and to communicate with the United States, Japan, Madagascar and the French colonies generally. This station, at the time the most powerful in the world, was handed over to the French War Department on Nov. 15 1920, and was formally presented to the French Government by Admiral Magruder, on behalf of the U.S. Government, about a month later.

The use of wireless telegraphy for civilian purposes in France may be said to date back to 1904, in which year the Post Office took over the naval stations at Ushant and Porquerolles, through which private messages to and from ships at sea were then transmitted. This service has been considerably developed, and in June 1921 nine stations were open in connexion with it—at Boulogne-sur-Mer, Havre, Ushant, La Bouscat (Bordeaux), Saintes-Marles de la Mer, Marseille, Cros de Cagnes (Nice), Bonifacio and Fort de l'Eau (Algiers). Other stations, such as Dunkirk, Dieppe, Cherbourg, Lorient and 'Ain el Turk (Oran) were also available to the public. Short-range stations were being established in mountainous districts so as to enable communication to be maintained in case of interference with the ordinary telegraphic circuits by snowfalls or other causes. There was also wireless communication between France and the principal islands on the coast. Messages to places abroad were sent from four stations—La Doua (Lyons), Croix d'Hins (Bordeaux), Basse-Lande (Nantes) and the Eiffel Tower and there were receiving stations at Villejuif, near Paris, Poitiers, Neuchâtel, Chartres, Basse-Lande and the Eiffel Tower. Communication by wireless had been established with the following countries:—

Europe:—Great Britain, Hungary, Yugoslavia, Bulgaria, Rumania, Norway, Austria, Poland and Turkey.

Asia:—China and Indo-China.

Africa:—French Colonies in northern, western and equatorial Africa and Madagascar.

America:—United States and West Indies.

All the stations available to the public are under the control of the Post Office, but the two great stations which were under construction in 1921 at Sainte Assise, near Melun, were to be worked, under Post-Office control, by the Compagnie Radio-France, an offshoot of the Compagnie Générale de Telegraphie Sans Fil, which had stations in various parts of the world. The rates, which are not yet definitely fixed, are generally about the same as those charged by cable companies but in some cases are less.

In addition to the two very powerful and modern stations at Sainte Assise, the French authorities had begun in 1921 to construct transmitting stations which would eventually form a great intercolonial system. Those at Saida (Algeria), Bamako (Upper Senegal), Brazzaville (Congo), Antananarivo (Madagascar) and Saigon (Indo-China) were to be completed in the summer of 1921. Others were to be established at Jibuti, Numea, Tahiti and Cayenne (Guiana).

*Aerial Navigation.*—Before the war the length of air journeys seldom exceeded 250 m. and very little extra weight could be carried. It did not seem likely that aviation could serve any real commercial purpose, at any rate for several years to come. The technical progress made under pressure of war necessities was, however, so great that every country which had taken part in the hostilities, and, through the force of circumstances, found itself in possession of a well-developed aviation industry, set to work to make the best use of it in the service of peaceful enterprise, especially as this new industry would be indispensable to military operations.

In 1919 French civilian aviation, then at its beginning, was controlled merely by a department of the War Office. This department soon developed into what was called the "Organe de coördination générale de l'aéronautique" under which the various scattered aviation services were placed. Aviation first obtained its autonomy by the creation, in Jan. 1920, of a separate Under-Secretaryship of

which they obtained their supplies. All this miracle of energy would have been impossible but for the alliance with Great Britain, whose naval supremacy enabled supplies and materials of all kinds to be imported. The natural result of the transformation of so many manufacturing plants into munition factories was to bring exports down to a very small figure, while imports increased by leaps and bounds. Simultaneously there was a decrease in the wealth derived from agriculture. Crops produced, on the average, only about half the normal amount. The wheat crop dropped from 90,000,000 to 49,000,000 quintals. The ports, which were much too small to deal with the vast quantities of goods brought from abroad, became congested. The Government departments were unable to handle the problems of supply which came before them. Under the pressure of necessity, supplies of all kinds were bought at any price. Ordinary notions of the value of money became obliterated. Freights, in consequence of the tremendous demand and the effects of the German submarine campaign, soared to fantastic heights and the Government was often forced to sign very costly contracts. The effect of all these abnormal conditions on the foreign trade of the country is shown in Table 22:—

TABLE 22. *Exports and Imports, 1914–8.*

| | Exports | | Imports | |
|---|---|---|---|---|
| | Francs | Metric quintals | Francs | Metric quintals |
| 1914 | 4,868,834,000 | 126,638,240 | 6,402,169,000 | 334,345,900 |
| 1915 | 3,937,369,000 | 40,910,750 | 11,035,794,000 | 320,492,560 |
| 1916 | 6,214,594,000 | 37,300,150 | 20,640,419,000 | 400,600,160 |
| 1917 | 6,012,698,000 | 30,111,240 | 27,554,055,000 | 348,326,080 |
| 1918 | 4,722,694,000 | 37,181,380 | 22,301,384,000 | 293,499,870 |

It appears from the table that the balance of trade which was 22% against exports in 1913, rose to 31% in 1914, 180% in 1915, 232% in 1916, 358% in 1917, and 372% in 1918.

Throughout the war France lived under a system of regulations and restrictions. It was absolutely necessary to prevent various kinds of produce, which were urgently needed in France, from leaving the country and international trade had to be interfered with so as to prevent the indirect supply of goods to the enemy, who tried in every possible way to neutralize the effects of the blockade. When hostilities ceased, it was found necessary to continue some of the war-time regulations and restrictions for a considerable time. The state of exhaustion, the collapse of production and the high cost of living, which the Government had to try to alleviate in every possible way, all made it impossible to return at once to freedom of commerce. The Government remained the sole purchaser of raw materials and of the necessaries of life. The position, however, improved very rapidly. The instinctive industry of the French people reasserted itself, and favourable symptoms were observed. Commercial treaties having been denounced, the Government could choose the Customs policy required by the altered circumstances. A decree issued in June 1919 restored the former freedom of importation to nearly all the articles hitherto prohibited, but at the same time the principle underlying the Customs tariffs was subjected to a radical alteration. The specific duties were replaced by *ad valorem* duties, but it was soon found that these were not satisfactory. In July of the same year the specific duties were restored but with various additions, styled coefficients. These extra charges, which were moderate at first, were steadily increased as the exchange and coal problems became more and more pressing. Actual prohibition was even resorted to (in April 1920). This policy—the outcome of French manufacturers' apprehension of competition from countries with still more depreciated currency—aroused great opposition, and finally increased coefficients superseded prohibition.

The revival in production was quite rapid in France, in spite of the coal shortage which prevailed in 1919 and 1920. Table 23 shows the improvement in the trade balance.

The result, which would have been still better but for the general economic crisis which occurred towards the end of 1920, show that a considerable effort towards recovery was made. The deficit in the trade balance, which was 20% in 1919, was

TABLE 23. *Exports and Imports.*

| | Exports | | Imports | |
|---|---|---|---|---|
| | Francs | Metric quintals | Francs | Metric quintals |
| 1919 | 11,879,600,000 | 55,643,800 | 35,799,267,000 | 384,471,685 |
| 1920 | 22,434,757,000 | 124,673,464 | 35,404,951,000 | 509,296,203 |

reduced to 58% in 1920. For the first time there was a decrease in imports, under the head of values though not of weights.

If we compare the quantities and not the values of goods exported by France, it appears that the total weight, which reached 220,000,000 quintals before the war, and which fell to the lowest figure on record, 30,000,000 in 1917, was a long way in 1920 from the 1913 figures. The increase in values is more apparent than real if the greatly enhanced prices of all commodities be taken into account. Although the tonnage entering French ports in 1920 was only 15% more than in 1913, the increase in values was 320 per cent. The export figures show a decrease of 44% in tonnage and an increase of 226% in values.

French trade with foreign countries in 1920 is shown in Table 24:—

TABLE 24. *Foreign Trade, 1920; in Francs.*

| | Imports from | Exports to |
|---|---|---|
| England | 6,746,959,000 | 3,311,943,000 |
| Germany | 2,658,429,000 | 1,180,261,000 |
| Belgium | 2,568,665,000 | 3,913,986,000 |
| Switzerland | 802,940,000 | 1,441,694,000 |
| Spain | 849,368,000 | 883,676,000 |
| Italy | 891,530,000 | 1,061,516,000 |
| United States | 7,061,721,000 | 1,770,892,000 |
| Brazil | 652,603,000 | 803,716,000 |
| Argentine Republic | 2,053,819,000 | 379,319,000 |
| Other foreign countries | 7,893,071,000 | 4,602,237,000 |
| Algeria | 960,475,000 | 1,926,906,000 |
| Tunisia | 218,628,000 | 318,429,000 |
| Morocco | 152,398,000 | 493,857,000 |
| Other French colonies | 1,894,345,000 | 647,232,000 |

In brief, the situation at the end of 1920 was that exports had not returned to the pre-war level and the inflation of imports had been only very slightly reduced. Smaller quantities of food-stuffs had been purchased abroad but there was an increase under the head of manufactured articles.

These conclusions were modified by the statistics for the early part of 1921. In the first four months of that year, the exports actually exceeded the imports. Compared with the corresponding period of 1920, imports showed a decrease of no less than 5,720,089,000 fr. and exports an increase of 1,111,940,000 francs. These figures reflect the conditions which affected trade and industry all over the world. They show how greatly the depreciation of a national currency acts as a stimulant to exports and a check on imports. The decreased imports of raw materials (3,578,000,000 fr. during the first four months of 1921 and 5,861,000,000 fr. during the corresponding period of 1920) illustrate the extent to which the industrial activity of France was reduced. On the other hand, the difference is not so great as it seems, in view of the fall in prices.

The future of France's foreign trade seemed in 1921 to depend very largely upon the amount of wisdom that might prevail in regard to Customs policy. Only the future could show whether there was to be pronounced protectionism, accompanied by heavy duties, or a system of treaties of commerce concluded for reasonable periods and relating to specified articles. Arrangements of this kind had been made with Canada and Czechoslovakia, and others were in course of negotiation (June 1921) with Spain, Switzerland and Poland. There seemed ground to hope that when the inflation of currency had been reduced and exchange returned to a more normal level, France would reap the fruits of the efforts she had made since the war to reconstitute her mercantile marine, improve her ports and navigable rivers, and stimulate her manufacturers to greater enterprise in foreign markets. Before the war, there was a tendency in France to attach exaggerated importance to the influence of capital. France was proud to be called "the banker

of Europe." She discovered by sad experience that this alluring title had brought nothing but loss and disappointment. The influence of capital did not prevent Turkey, a country to which France had lent vast sums, from going over to the enemy, and the still vaster sums advanced to Russia had also been lost, apparently beyond recall. It would not be surprising if the result of this object-lesson were to convince the French people that it is better to work and produce than to live on the interest of one's money, and that they had it within their power to become a great manufacturing country with an important share in the world's trade. (G. A. R.)

### Finance, 1909–21

French finances underwent such changes during the World War that in 1921 there seemed to be no relationship at all between the present-day budgets and those of 1909–10, so enormously had figures been swollen, taxes increased, and their nature modified. From this latter point of view the whole French fiscal system has been changed. Up to the eve of war direct taxation was levied in France, following the principles of the first revolution, in accordance with external signs of wealth, chiefly in accordance with the letting value of the tax-payer's residence. This does not mean that capital was not touched. Taxation was levied in the form of inheritance duties on the whole of an estate, on the transfer of house property, and securities were taxed annually on the income, and by imposts on stock-exchange transactions. A few weeks before the opening of hostilities a global income tax was introduced, of the modest amount of 2%. The execution of this measure was delayed, but in 1916 it was put into operation, the figure rising rapidly to 12% and then 20%. The law of June 25 1920 brought the maximum up to 50%, with a sliding scale, making this super-tax of 50% only applicable to that portion of incomes exceeding 550,000 francs. In 1917 a further tax was introduced which varied according to whether the income was derived from agriculture, professions, etc. Thus the old system, which had been applied for over a century, and which, although frequently modified, had subsisted in its first conceptions, had given way to a new system which, although more in conformity with modern theories, could not in 1921 be said to be as solidly founded as was its predecessor.

I. *The System of Taxation.*—The system of taxation until 1914 was formed by four kinds of taxation. 1. The so-called direct contributions—that is to say, levied on four kinds of external signs of wealth, namely (*a*) revenue from land and house property, (*b*) doors and windows, (*c*) the personal figure arrived at by the letting value of the house or flat occupied by the tax-payer, and (*d*) license tax paid by traders, manufacturers, and some of the liberal professions, which varies according to occupation. 2. The so-called indirect contributions consisting of fixed or proper proportional duties, levied (*a*) on the transfer of property, (*b*) on the emission and negotiation of stocks and shares, and (*c*) on private contract notes. 3. Consumption taxes, levied on French produce, such as alcohol, wine and sugar. 4. Customs duties, levied on a large number of imports.

Direct contributions were reformed by the law of July 31 1917, which suppressed the taxation on personal property, doors and windows, and licences, and placed a tax on different categories of income. A tax is placed on industrial and commercial profit made during the preceding year. It is levied upon all concerns belonging to one person, globally, either at the head office, or at the office of the chief person concerned.

The tax is calculated on the net profit of those companies which are by law bound to communicate their balance-sheets to the registry office, and upon those individuals or companies which, before April 1 of each year, have furnished the authorities with a summary of their profit and loss account. In the absence of a declaration the taxable profit is fixed by applying an appropriate coefficient to the turn-over of the concern. The fixed tax of 4·5% was raised to 8% by the law of June 25 1920. An annual tax of 3·75%, raised by the same law to 6%, is placed upon agricultural profits, which are considered as being equal to half the rental value of the land. If, however, the real profit does not reach half the rental value the taxpayer is entitled to a proportionate reduction. Incomes of over 1,250 fr. from this source are taxable, and no declaration of income is required. Incomes derived from public or private payment, salaries, annuities, etc., are subject to a tax of 3·75%, raised to 6% by the law of June 1920. In fixing the taxable figure the net value of such payments, whether they be in money or kind, is taken into account. Employers, whether they be companies or individuals, are required to furnish the authorities with a list of their employees. People engaged in professions, or in other occupations which are not subject to special income tax have to pay 6 per cent. Interest from mortgages, loans, and bank deposits is also taxed.

Such are the chief provisions of the law which has established a schedular income tax in France. While it has suppressed former taxation, the old forms of taxation still exist as the basis of local taxation, and will do so until new laws have been voted.

A fresh tax is that on the turn-over (*chiffre d'affaires*) which is levied on all businesses in France save the selling of bread, the products of State monopolies and, of course, stamps and stamped paper issued by the Government. Further exceptions are made in favour of those trades and businesses whose prices, charges or commissions are fixed by public authorities, such as marine brokers, stock brokers, chemical manufacturers, insurance companies, public entertainers and public carriages. Exception is made in these cases because enterprises of this kind are already taxed in other ways. The *chiffre d'affaires* tax is fixed at 1%, a tenth of which goes to the department and the commune. The various imperfections of this tax have led to certain alterations which were adopted by Parliament in June 1921.

II. *The Budgets.*—The Budget on the eve of war, 1914, in millions of francs was as follows:—

| Expenditure | | Revenue | |
|---|---|---|---|
| Public Debt | 1,318 | Taxation | 3,616 |
| Salaries of Public Officers | 19 | Monopolies | 1,005 |
| General Administration Services | 3,336 | Domains | 64 |
| Regie | 651 | Budgetary Sundries | 68 |
| Restitution | 49 | Extraordinary Revenue | 507 |
| | | Receipts (*recettes d'ordre*) | 111 |
| | | Algerian credit | 2 |
| | 5,373 | | 5,373 |

With this may be compared the ordinary Budget of 1921:—

| Expenditure | | Revenue | |
|---|---|---|---|
| Public Debt | 11,248 | Taxation | 13,901 |
| Salaries of Public Officers | 39 | Monopolies | 2,526 |
| General Administration Services | 8,877 | Domains | 145 |
| Regie | 2,455 | Budgetary Sundries | 157 |
| Repayments and Restitution | 129 | Extraordinary Revenue | 5,200 |
| | | Algerian Credits | 6 |
| | | Alsatian-Lorraine Credits | 408 |
| | | Receipts (*recettes d'ordre*) | 494 |
| | 22,748 | | 22,837 |

In presenting the Budget of 1913, which did not reach 5,000 million fr., M. Klotz told Parliament that he begged his colleagues to reduce the demands of their departments to what was strictly necessary. He analyzed an increased credit of 167 millions due to military expenditure, social demands, and the development of national equipment. Justifying the demand for the army he pointed out the advantages given to soldiers serving more than their legal time, the allowances given to those supporting a family, the placing of officers in a special reserve, the reorganization of the artillery and of medical officers, premiums given to motor-lorry owners, increase in the pay of officers, increased assistance to old soldiers, increased cost of living and of material, and the increases in the budget strength of men and horses. The social programme comprised demands for the Ministry of Labour, for compulsory insurance and for increase in the benefits of voluntary insurance; help for mutual societies and advances for building societies. Public works called for large sums for the improvement of internal waterways and seaports. The full programme for the former amounted to 440 million francs.

The ordinary budgets of 1914 and of 1921, it will be seen, balanced. The latter, however, almost five times as big as that of 1914, only balanced thanks to 5,200 million fr. of extraordinary revenue derived from the war profits tax and the disposal of war stocks. The ordinary budget of 1921 has also, side by side with it, an extraordinary budget of 3,000 millions, entirely covered by loan resources, and a budget of recoverable expenditure, under the terms of the Peace Treaty, by which Germany and her allies had become responsible. This budget comprised the sums necessary for reparation of war damage, caused among others to civilians who lost in life or limb or were victims of any act of cruelty which has lowered their health, their capacity for labour, or touched their honour; to prisoners of war who have been badly treated. Germany also owed pensions or compensation to the military victims of the war, wounded, sick and invalided, the amount of the sum being the capital value of pension or compensation due to them; the cost of relief given to prisoners of war and their families, allowances given to the dependents of mobilized men, the losses incurred by civilians who were obliged to work without pay, and all damage done to property.

According to the Treaty of Versailles the Reparation Commission had to fix the total debt to Germany as it did by the prescribed date, May 1 1921, the figure being 132,000 million marks (gold), to which was added the sums lent to Belgium by the Allies; Germany was to pay an annual interest charge of 5% on the debt, and 1% for amortization. The annual payment was to be 2,000 million marks (gold), and a sum equal to 26% of the value of German export trade. The complete annuity, that is to say, 6% on 132,000 million marks, would amount to 7,920 millions. If Germany was to reach this figure her total export trade must amount to nearly 25,000 million marks (gold). The French share of the moneys obtained from Germany being fixed at 52%, it is easily seen how small a sum she would obtain to meet the charges arising from the reconstitution of the devastated regions and the payment of pensions. These figures for the year 1921 were (in millions of francs):—

| | |
|---|---|
| Ministry of Finance | 3,827 |
| Justice (Judicial and Prison Services) | 1 |
| Foreign Affairs | 2 |
| War | 14 |
| Public Instruction | 244 |
| Fine Arts | 30 |
| Technical Instruction | 1 |
| Colonies | 1 |
| Agriculture | 9 |
| Public Works | 393 |
| Posts and Telegraphs | 26 |
| Merchant Shipping | 14 |
| Liberated Regions | 10,231 |
| Pensions Services | 1,737 |
| Hygiene | 10 |
| | 16,540 |

The expenditure of the Ministry of Finance comprised pensions to invalids, widows and orphans; allowances to elder relatives; pensions to civil victims of the war; the salaries of the staffs employed by these different services; the reconstruction of documents destroyed during the war; the reinstallation of administrative services in the liberated regions; and of tobacco manufactury of Lille. The Ministry of Justice had to meet the expenses of reconstituting the *Actes de l'Etat Civil*; the register of mortgages; of repairing the damage done to prisons and other institutions. The Ministry of War had to meet the charges arising from the repair of barracks and other necessary buildings. The Ministry of Public Instruction had charge of the central and departmental orphanages, and had on its books at the beginning of 1921, 587,000 children, who, at 360 fr. a head, would cost 211 millions; 120,000 more children were to be adopted. Fine Arts would require 30 millions for the protection and repair of monuments and public buildings damaged by war. The claim of the colonies arose from the losses suffered by Mahommedans. The Ministry of Agriculture had to repair a number of institutions such as the agricultural school of Rethel and the industrial schools at Douai, and make good the havoc wrought in the forests. Public Works required 190 millions for road building and other works, 70 millions for the rebuilding and working of electrical power stations in the liberated regions, 90 millions for canals, 50 millions for railways in the north and the east, 83 millions for extraordinary expenditure on Alsace-Lorraine railways, due to the condition in which they were left by the Germans. The Ministry for the Liberated Regions claimed 10,231 millions, a sum which was reduced by Parliament to 9,000 millions; 7,000 millions of this would go in payment of war damage and advances for industrial reconstitution; 140 millions were devoted to relief for the inhabitants; 720 millions to works undertaken by the State; 220 millions for transport. These figures give but a general idea of all the work that had to be accomplished in the devastated districts. The Ministry of Pensions required 28 millions for the staff and central administration; 1,470 millions for advances on pensions and bounties; and 4 millions for the relief of the families of the killed.

These 16,000 million francs of expenditure had to be added to 20,000 million already granted for the same purposes, as recoverable expenditure, in the financial year of 1920. It was thus a total of nearly 37,000 million francs that France had already advanced in two years to the account of Germany.

Apart from these budgetary credits other expenditure swelled the total, which, capital and interest included, was estimated to be 60,000 million francs on May 1 1921.

The key to the financial situation of France is in this budget of "recoverable expenditure." Had Germany carried out her undertaking; that is to say, had she paid to her conquerors a sum corresponding to the admitted damage done, the situation of France, although still serious, would not have been one beyond her power to face. By working energetically, as she had begun to do, at reducing expenditure, and perfecting the system of new taxation, France should be able to have a regular revenue of 20,000 millions to balance expenditure, which ought to be brought down to that figure. To do this, the various new services which were created during the war, and which in different ways had led to excessive expenditure, must disappear. The coal and wheat control must be got rid of, and the State merchant fleet sold as quickly as possible. The railway budget must be balanced; all useless expenditures suppressed, and only the most urgent public works, or those likely to be productive within a very short space of time, undertaken.

Meanwhile, awaiting the settlement of the debts of Germany, the French Treasury in 1921 had to meet the following charges in thousands of millions of francs:—

| | |
|---|---|
| Ordinary Budget | 22 |
| Extraordinary Budget | 3 |
| Recoverable Expenditure | 16 |
| Supplementary Credits | 2 |
| Repayment of Foreign Debt | 6 |
| Deficit on Prev'ous Budgets | 7 |
| Special Account | 3 |
| Railways | 1 |
| Repayments to the Bank of France | 9 |
| | 67 |

III. *The State Balance Sheet—Railways.*—It is possible to do for the French State what is done by every individual and every company: that is, simply to draw up a balance sheet, to make a statement of the State's resources and commitments, of its credit and debit. Naturally we do not, as in the case of private concerns, find that the credit equals or is greater than the debit. The fundamental and essential source of a modern State's revenue is taxation levied on its citizens. Its real wealth, therefore, lies in the individual wealth of the latter, and consists in their sum total. Nevertheless, apart from this resource of annual tribute, the State possesses a domain which varies in importance according to the nation, and which does represent something. It is only the paying elements of such a domain which can be usefully entered on a balance sheet.

France possesses her sea coasts; land which in certain parts has been left by the sea; her lakes, rivers and navigable streams; canals; ports; forests, national roads, and the bridges and other works connected with them; public buildings, palaces,

museums, chateaux, Government offices, parks and gardens. The State also owns railway lines, the exploitation of some of which has been conceded to private companies, while the State itself runs others, some of which it has built, others of which have been bought back from the companies before the expiration of their concessions. The buildings in which public services are housed might be looked upon as an active resource if, in drawing up the accounts of each of those services, they were debited with an annual rent. But such is not the case. The postal service, for instance, is not debited with the rent of the public buildings which it occupies, nor even with that of buildings leased by the State in certain towns for the accommodation of posts and telephones. The postal service is not debited with the wear and tear of the telegraphic and telephonic wires, nor with the wireless telegraph stations which it uses every day. In fact, no accounts of this sort are kept for any of the public services. All the prefects and sub-prefects, the courts of justice, troops, occupy premises the rental of which does not figure in the accounts of any of the ministers concerned. The seashore and the dried beds of changing rivers are so little exploited that they need not be taken into account. Land and river communications might produce revenue worthy of figuring in a balance sheet, were tolls taken. The tolls which existed a few years ago have been abolished, and traffic is everywhere free; it is the budget which keeps up the roads, rivers, canals and ports. In the ports certain dues are levied on shipping for the profit of the State, the municipalities, and the chambers of commerce which have participated in the cost of the harbour works. Although some receipts are obtained from these sources, they do not represent realizable wealth. The forests of the State domain, however, are both productive and alienable. It is clear, nevertheless, that they cannot be given up. Both from the point of view of health, and general security, they ought to belong to the community; but they are a realizable asset. Twice before, in 1848 and 1870, they were given to the Bank of France as security for loans to the Treasury. The value of the year's output figures in the budget of 1921 was estimated at 57 million francs. The chief national asset is formed by the main railway lines, which in 1921 had a length of about 50,000 km., and represent an installation cost of at least 25,000 million francs. In spite of the importance of the sums thus spent in railway construction the Treasury has derived no profits. It has to be remembered in this respect how great, in France and elsewhere, was the upset caused in railway administration by the war. Before 1914 the five private companies, the Eastern, the Paris-Lyons-Mediterranean, the Northern, the Orléans, and the Southern railways, had gross revenues which exceeded their expenses. The Northern, P.-L.-M. and Eastern even showed a profit both with their preference and ordinary shares. The Orléans and the Midi lines had to avail themselves of the guarantee of the State which made them a varying annual payment. The Western railway, exploited by the State itself, was in very much less favourable position. The proportion of expenditure to revenue was much greater than that of the least successful private worked line. War changed this situation profoundly. Part of the Eastern and Northern systems had been destroyed, and those two companies had had to spend vast sums in rebuilding their lines. Other causes had upset railway accounts. The Eight Hours' Day law had been rigorously interpreted and had led to a great growth in the staff. Excessive increases in salaries and wages had been made. In spite of raising the tariff, which had been done by decree on several occasions, a deficit was shown each year, that of 1920 being not less than 3,300 millions.

A Convention had been signed between the Ministry of Public Works and the six railway lines, the State railway coming in on the same footing as the private companies, but this Convention had not yet been approved by the Senate. In theory it should do away with the deficit, as it enables tariffs to be raised until receipts and expenditure balance, and the companies making any surplus pay it into a common fund so as to equalize revenue. Meanwhile the railway companies were a heavy burden on the budget. It was indispensable that expenditures should be cut down, and it was impossible to count only upon raising the tariffs to balance the railway budgets. For goods traffic of many sorts the existing rates were already prohibitive, and traffic of many kinds of merchandise had either slackened off considerably or had stopped. The scheme of having a common fund was therefore far from being the final remedy for the present evil.

A few figures will show the contrast between the pre-war and the post-war conditions. The total length of railway lines exploited by the State and the five big companies was 41,000 km. The deficit in 1913 was 80 millions francs. In 1920 it amounted to 3,200 millions. Of the five private companies, gross receipts rose from 1,693 millions in 1913 to 4,467 millions in 1920. The net yield of 696 millions became a deficit of 1,081 millions. The charges of 986 millions added to this last figure give a general deficit total of 2,067 millions. The working coefficient has passed from 59% to 124%. In 1921, therefore, this large railway system, far from producing revenue, laid a heavy burden on the budget.

As a matter of fact, when one comes down to analyse the actual elements of the real property of the State, there is nothing which corresponds to the fortune of an individual.

Railways, as we have seen, are not revenue-producing. The Western railway belongs to the nation. It consisted in 1921 of lines bought about half a century before, and of the old Western company system which was bought at the beginning of the 20th century. It had for long shown a deficit. The Treasury had still annual payments to make to complete the purchase of the first State line, and to pay off the shares and stocks of the Western company, which would be finished in about 30 years' time, and to pay the 4 and 5% interest on the bonds issued by the Treasury in order to meet the expenses of the system. The State was half proprietor of the lines leased to the five big companies, and would become again full proprietor within the next 30 or 40 years at most. It would then own some 40,000 km. of railway line which would have no more capital charges to support, since the stocks and shares would have been paid off. (The concession to the Northern line expires on Dec. 31 1950; the Eastern on Nov. 26 1954; those of the West and of the Orléans lines on Dec. 31 1956; the P.-L.-M. on Dec. 1 1958; and the Southern on Dec. 1 1960.) This was the situation in 1913, but since then the Northern and the Eastern companies had had to meet an expenditure amounting to many thousands of millions, due to war damage: running costs had risen in a quite unexpected manner, and the situation was not the same as when favourable working costs made it possible to foresee the time when the companies, no longer availing themselves of the State guarantee of their interest, would in some cases share profits with the Treasury, or at any rate would be able to amortize their capital by the period laid down, so as to hand over their systems to the State between 1950 and 1960, free of all capital charges. It was impossible in 1921 to foretell what would be the results of the new convention, but at the best it would be a long time before railways ceased to weigh upon French finance. It would be a very fine result if they could only manage to earn enough revenue to balance their working costs and capital charges.

A close study of the proposed Convention shows that enough had not been done to provide for reduction of working costs. It only laid down that, when working costs move up, tariffs must follow suit, until expenditure is covered, but in that case Parliament will have to forgo its right of fixing maximum rates. If those maximum rates are prohibitive they will reduce or stop traffic, and the State will have to subvention the common fund of the railways. It is hoped to stave off this unfortunate event, by giving the railway companies a management bonus. First of all there should be a definite settlement of accounts during the war period. When this had been done it might be possible, with some modifications, to go back to the railway conventions of 1883, which really did encourage the railway companies to work their lines properly. The chief resource of the Treasury, therefore, was in taxation.

IV. *Foreign Trade and Exchange.*—One of the results of the World War was to extend the finances of the belligerents beyond

their own frontiers. Nearly all the nations engaged had to consider not only their expenditure at home, but also what they were forced to incur abroad, and to calculate the resources which might meet this situation and the subsidies which had to be furnished by one Ally to others.

France more than any other community suffered this necessity, for the double reason that she had to support a greater military effort and that a part of her territory was invaded. Also, from the very beginning of hostilities, she was deprived of her principal coal-fields and factories in which an essential portion of her metallurgic industry was concentrated. All her male population between 20 and 50 years old was called to the colours, and she had no agricultural labourers left nor workmen for her manufactories. She had therefore to import from foreign countries enormous quantities of food, coal, arms and ammunitions. Throughout the war her imports continued to grow, while her exports decreased and fell considerably below what they had been in 1913. This can be seen by the figures of her foreign commerce (in millions of francs):—

| | Imports | Exports | Balance of Imports |
|---|---|---|---|
| 1914 | 6,402 | 4,868 | 1,534 |
| 1915 | 11,035 | 3,937 | 7,098 |
| 1916 | 20,640 | 6,214 | 14,426 |
| 1917 | 27,554 | 6,012 | 21,542 |
| 1918 | 22,301 | 4,722 | 17,579 |
| 1919 | 35,799 | 11,879 | 23,920 |
| 1920 | 35,404 | 22,434 | 12,970 |
| 1921 (Four months) | 7,118 | 7,400 | 282 |

A glance at this table explains why France had to contract the enormous foreign debt of which the details have been given earlier. This table also gives the key to the persistent rise in exchange with various countries which reached its height in the course of 1920. The acquisition of this enormous extra amount of merchandise involved the purchase of a corresponding quantity of foreign moneys, far exceeding French credit in the countries concerned. It was this which caused the rise of the pound sterling to 68 fr., and of the United States dollar to 17 francs. In the first months of 1921 the situation was greatly changed, owing to the rise in the quantity of exports. The changing in the commercial balance was immediately reflected in an easing of the tension in exchange. In May 1921 the pound sterling fell below 47 fr., and the dollar to less than 12 fr.

Another element contributed to the condition of exchange. This was the circulation of notes of the Bank of France; when that circulation increased, prices and exchange both rose. It progressed in the measure indicated below (in millions of francs):—

| | |
|---|---|
| End of 1913 | 5,713 |
| " " 1914 | 10,042 |
| " " 1918 | 30,250 |
| " " 1919 | 37,274 |
| May 6 1921 | 38,832 |

Thus, as with foreign trade, it was after the Armistice that the balance was most completely upset. The increase in French circulation of notes was greatest at that moment, that is, during the same year that French imports touched their culminating point. Subsequently the circulation remained almost stationary.

(R. G. L.)

*War Money.*—At the outbreak of war, in July 1914, panic and the hoarding instincts of the population led to the complete disappearance not only of gold but of all silver and gradually even of copper coinage. The lowest note then in circulation was of 50 fr., and the immediate crisis was met after a while by the issue by the Bank of France of 5, 10 and 20-fr. notes. The output of the Mint was increased but immediately absorbed. The State being unable to meet the situation, municipalities, chambers of commerce, public companies, and even private individuals, were forced to manufacture their own small change. There was only one department, that of the Hautes-Alpes, in which none of this war money was issued. This currency was of four different kinds: (1) The notes and tokens of cardboard or metal issued by municipalities, chambers of commerce, and tradesmen in the non-invaded districts of France. (2) The notes issued by invaded communes, by invaded towns or groups of towns. (3) The Alsace issues. (4) The notes and tokens used in prisoners' camps and camps of concentration and internment. In the non-invaded districts it was usually the municipality or the chamber of commerce which issued the notes, which were guaranteed by a deposit in the Bank of France. In the invaded districts it was the towns themselves which guaranteed repayment. In Paris it was not until March 1920 that the chamber of commerce decided to issue small notes of the denominations of 2 fr., 1 fr., and 50 centimes. By that date the small-change crisis in Paris had led to very considerable discontent. All sorts of efforts had been made to meet it: stamps had been enclosed in celluloid discs; the big hotels had issued their own metal or cardboard tokens; big works were paying small amounts to their employees with similar vouchers; in clubs the ticket system was in force. The artistic merit of the notes was nowhere very great; the paper used was generally bad, and there was a considerable profit for the issuing establishments arising from the large numbers of notes which were torn, lost, or absorbed by the vast number of collectors and souvenir hunters.

(R. G. L.)

### The Invaded Regions

It is almost impossible to paint a general picture of the conditions which prevailed in the occupied territories of France during the war, martial law being capable of the most varying interpretations according to circumstances and the character of the men called upon to administer it. The story of Lille, which was occupied by the Germans from Oct. 13 1914 till the eve of the Armistice in 1918, gives a general idea of the conditions under which the French in occupied territory lived throughout the war.

It should be noted first of all that nearly everywhere the Germans preserved the existing local municipal bodies. At times, however, as at Cambrai, on Jan. 5 1915, without in any way consulting the inhabitants, they changed the composition of the municipal bodies. It should also be added that in the very large majority of cases, mayors and municipal councillors, although able to flee from the enemy, remained behind to perform their duties at their posts. When the Germans entered Lille they appointed Gen. von Heinrich as governor. He had under him the Gen. von Grävenitz. The first step taken by the Germans was to call upon the population under pain of death to deliver to the *mairie* all arms, munitions and explosives in its possession. Motor-cars had to be handed over, and troops billeted and fed. Meetings of more than five persons were prohibited; restaurants had to be closed by 9 P.M., which was curfew for all inhabitants. During the day the shutters of all dwelling and business houses had to remain open. Hostages were taken for the good behaviour of the population, among whom were the prefect, M. Trepant, and Bishop Charost. At the start, these hostages had to sleep at the Citadel, being split up for this purpose into six batches. This method was abandoned on Dec. 31 1914, but was readopted on July 3 1915. Three weeks later this form of petty tyranny was given up, and the hostages were instead ordered to report twice a day in person at the *Kommandantur*. It was not until Oct. 5 of the same year that this formality was dispensed with. Throughout the whole period of occupation a rain of regulations fell upon the town from the military police. People guilty of the slightest breach of any one of these many decrees were subject to severe penalties rising from fine to imprisonment. Those penalties were inflicted in the most ludicrous cases. Thus there were sentences of four days' imprisonment passed upon inhabitants whose timepieces were not regulated on German time. Policemen and civilians had to salute all German officers above the rank of a sub-lieutenant; bicycles had to be delivered to the Germans, under a penalty of a 300-mark fine or three months' imprisonment. The exchange value of the mark was declared to be fr. 1·25. In Dec. 1914 certain boundaries were traced in the town, across which the inhabitants must not go. In Feb. 1915 all written communications, even with localities behind the German lines, were forbidden. Naturally, wireless telegraph installations were confiscated, and it was forbidden to pick up newspapers dropped by Allied aeroplanes upon the town. The governor decreed in 1915 that there should be a census of all water-wells; that horses should be reexamined with a view to their serving in the army, and that all proprietors of vehicles and harness, as well as of photographic apparatus should declare them. Von Grävenitz, who was responsible for the institution of passes,

without which it was impossible to leave Lille, decreed that they should be delivered on payment of one franc, and were valid for six weeks for daily journeys between Lille and the nearest village. Every inhabitant of the town who desired leave had to have one of these passes and also an identity card which the German police could demand at any moment. Failure to produce such a card involved a fine varying between 3 and 30 marks, or 2 or 3 days' imprisonment. Even inside the town itself, it was difficult to get about, because of a decree issued in March 1915 prohibiting motor-cycle and motor-car traffic. From the start, the town was forced to feed the troops of occupation, and von Grävenitz, in a decree (Nov. 23 1914), took pains to lay down the menu. Thus, an officer's lunch had to consist of soup, two meat and two vegetable dishes, cheese, dessert, and half a bottle of wine. Non-commissioned officers got no cheese, and beer instead of wine. The inhabitants upon whom troops were billeted had to bear the cost of lighting, heating and laundry. It is hardly necessary to add that the municipality found it almost impossible to see that these copious menus were provided; indeed, for a time the occupied districts were threatened with famine. In Feb. 1915 the meat ration was cut down to 150 grammes per head, and it was only through relief work of the Dutch Government and a Spanish-American committee that the civilian population obtained food.

On Jan. 19 1916, all Frenchmen in the town between the ages of 17 and 60 had to register themselves on a penalty of imprisonment. The people were prohibited from standing at their windows and from travelling by tramway without special permit. On Nov. 4 1914, it was decided that Lille should pay an indefinite sum. Payments on account were to be made as follows: Nov. 10 1914, one million francs; Nov. 17, 2 millions; Nov. 24, 3 millions, and the indefinite remainder by Dec. 1. The mayor and the bishop did their utmost to raise the money demanded by the enemy, and paid the first two millions. They were unable to obtain the third million, and von Heinrich agreed to accept a total payment of seven millions on Dec. 1.

*Damage and Reconstruction.*—The best way of showing the extent to which the ten invaded departments of France suffered from the war, and the effort made to repair the damage done, is to compare pre-war statistics with figures taken at the date of the Armistice and on Dec. 31 1920. The ten departments concerned, those of the Aisne, Ardennes, Marne, Meurthe-et-Moselle, Meuse, Nord, Oise, Pas-de-Calais, Somme and Vosges, had, when war was declared, 6,523,260 inhabitants, or 16% of the total population of the country, paying 18% of the total taxation. They formed the richest portion of France: rich in resources, in artistic treasures and historical associations. Lille, Cambrai, Turcoing and Arras were, before invasion, daily increasing the value of their textile, metal, glass and alimentary industries, while the mines of those regions yielded 90% and 55% of the total output of iron and coal respectively. There were 11,500 works, producing at full working 83% of the pig iron, 94% of the woollens, 90% of the linens, 60% of the cottons and 70% of the sugar output of France. Altogether there were 25,763 industrial establishments, with a rental value of 108,200,000 fr.—a third of the rental values of the whole country. The smaller metal trade alone employed 100,000 workmen. In the Meurthe-et-Moselle the iron industry employed 38,000 people, and kept 76 furnaces going. Power stations produced 300,000 kilowatts of electrical energy, or nearly 50% of the total. Trade and agricultural communications were insured by a splendid system of roads and railways, with many bridges and viaducts. It was the most flourishing and the best-equipped part of France.

When the Armistice was signed 1,400,000 people had been killed, 800,000 crippled, and 3,000,000 wounded. Municipal life had ceased in 3,256 of the 3,594 communes occupied by the enemy. Nearly 4,000,000 hectares of land had to be put in order again, of which 1,757,000 hectares were agricultural. There were 265,000,000 cub. metres of trenches to fill in; 300,000,000 sq. metres of barbed wire to pull up; nearly 300,000 houses to be rebuilt completely, and about the same number to be repaired. Shell-fire had damaged 3,296 schools, 2,671 churches, 2,447 *mairies*, and 49 hospitals; 523,000 milch cows 469,000 sheep and goats, and 367,000 horses, donkeys, and mules had been carried away by the Germans. Two-thirds of the area and productivity of the coal-fields of the departments of the Nord and the Pas-de-Calais had been destroyed; 220 pits had to be reconstructed. The Lens-Liévin-Carvin-Meurchin and Drocourt (Pas-de-Calais) fields were completely destroyed, and the workings were flooded. The destruction done to the coal mines was estimated at 880,000,000 francs. The majority of the power stations had either been systematically destroyed or emptied of their material, the resulting damage amounting to 210,000,000 francs. Of 200 gas works 150, serving 323 towns had been damaged to the extent of 60,000,000 francs. In the iron trade, in the department of the Meurthe-et-Moselle alone 50 blast furnaces had been badly damaged or completely destroyed. Foundries and rolling-mills had been either stripped of their equipment or destroyed on the spot. As typical examples of German devastation there were the steel works of Denain-Anzin (Nord), of Homécourt (Meurthe-et-Moselle), and Mont-St. Martin. The first establishment, which had 8 blast furnaces, 3 Martin and 1 Thomas steel plants, and 20 rolling-mills, in 1914 produced 400,000 tons of pig iron, the same amount of steel, and 350,000 tons of finished goods. The Germans left of it nothing but a heap of ruins. At Homécourt only the skeleton of 7 blast furnaces remained; the Thomas plant was blown up by dynamite; the Martin plant was taken to pieces and removed to Germany; the rolling-mills and electric plant were smashed. At Mont-St. Martin, where the installation had cost 8,000,000 francs, the buildings were emptied of their contents and destroyed. The iron and steel trade suffered losses estimated at 2,300,000,000 francs. The minor metal trade losses amounted to 1,100,000,000 francs.

Terrific havoc was wrought in the textile industries by shell-fire, by pillage, and through destruction by the retreating enemy. In the region of Fourmies (Nord), where there was no serious fighting, of 74 works 6 only appeared to be workable, and those only after very great repairs. The other 68 had either been burned, demolished, or emptied of their equipment. At Lille, Roubaix, Tourcoing, the same systematic pillage had taken place. Armentières, which had 8,000 looms before the war, was nothing but a heap of ruins. At Sedan, the centre of the cloth trade, only 15 looms were in working order. Together with the cost of the buildings destroyed, the damage amounted to 950,000,000 francs.

The importance of the agricultural-alimentary industries of the devastated regions before the war can be measured by the fact that they absorbed one-third of the motive power used by the whole industry throughout the country. Of 214 sugar factories in existence before the war, no less than 145 had suffered. The buildings of 90 of them had been destroyed, and the machinery of 130. Eleven refineries and 72 distilleries had been completely demolished. The brewing industry suffered heavily. Of the 2,825 breweries in France in July 1914, over 1,800 were destroyed, pillaged, or emptied of their machinery. The total loss suffered by this industrial group was estimated at 600,000,000 francs. The glass, mirror and crystal and chemical industries suffered losses amounting to 800,000,000 francs. There were many quarries in the devastated regions. Their losses amount to about 20,000,000 francs. The tanneries, of which there were 141, working 1,248,600 skins a year, suffered damage amounting to 25,000,000 francs. To this long list of ruins to be repaired must be added 52,000 km. of roads, 2,400 km. of railways, and 3,500 bridges and viaducts. Over 3,500 industrial establishments had been destroyed or badly damaged; 2,000,000 families had been ruined; 2,700,000 people had been driven from their homes. Never before had a country been called upon to repair such a mountain of ruin.

Undismayed by the magnitude of the task and the countless difficulties at the start, France immediately took in hand the work of reconstruction. The first great difficulty was the provision of labour, with so many killed, so many still suffering from wounds and the shock of war. Material was also lacking in a

country exhausted by four years of a war to which all its energies had been devoted. Rapid transport was necessary, but impossible to expect from a railway system and a rolling stock worn out by war service. Added to these difficulties there were the crises of exchange and credit, and the financial strain due to the cost of war and lower yield of taxation. Also the French merchant marine had been reduced by a third. The following statistical information will show the intensity of effort made.

The population of those districts which were directly affected by the war, which in 1914 was 4 676,398, on Nov. 1 1918 was 1,944,000, rose to 3,524,600 on Nov. 1 1919, and to 4,066,397 on Dec. 31 1920. (It has to be borne in mind, in considering these figures, that there were large tracts of country which, although invaded by the Germans, either did not remain long in their occupation or did not suffer greatly from war or deliberate destruction.) By the end of 1920 municipal life had been resumed in 3,216 out of 3,256 communes. Of 6,690 schools open before the war, with 580,467 attendants, 6,613 had reopened, with an attendance of 397,978 children. Shells had been removed from 3,415,239 of the 3,800,000 hectares to be put in order; 218,934,793 cubic metres of trench had been filled in; 249,014,302 sq. metres of barbed wire had been removed. The first furrows had been traced on 2,000,000 hectares. Of the 42,100,000 cubic metres of ruin, 26,172,495 had been cleared. By the end of 1920 280,825 of the 600,000 houses destroyed or damaged had been rendered more or less habitable, although endless difficulties with labour and material had prevented solid reconstruction of the necessary housing. The Government had endeavoured to meet the housing difficulty by building temporary cottages and huts; 41,128 wooden huts, 60,605 temporary wooden cottages, and 29,860 temporary houses, made of débris, had been provided, thus giving housing to 1,685,883 people.

By 1921 26,000 km. of roads had been rendered practicable, and 8 000 km. had been repaired Nearly 4,000,000 tons of material had been used on metalled roads; 1,980 bridges, mainly temporary, had been built; and all the main railway lines had been got to work; 1,220 out of the 1,503 bridges and railway viaducts on those lines having been repaired. Of the 2,385 km. of local lines which had been damaged, 1,805 had been partly repaired, and 675 were again in working order, with 191 temporary and 183 permanent bridges built. Destruction of the waterways had almost been made good.

Very great results had been obtained by the Government in restoring the agricultural wealth of the liberated regions. Of the 1,757,000 hectares of arable land to be restored to cultivation, by 1921 1,700,000 had been levelled and 1,400,000 broken up. In the autumn of 1919 and the spring of 1920 a total area of 961,578 hectares had been sown as follows: wheat, 304,924 hectares; barley, 37,579; rye, 39,444; oats, 334,495; beets, 57,709; potatoes, 46,432; other crops, 140,995. The results of the effort towards agricultural reconstitution exceeded all expectation. The ten liberated departments in 1921 were self-supporting, from the point of view of cereals, and it was possible to foresee in the near future that the rest of the country would be able to benefit from their surplus supplies. While this fine result was no doubt mainly due to the tireless energy of the peasant population in the north and east, the Government itself deserves some of the credit for what was done. A special department (*Service de la Moloculture*) broke up 275,670 hectares; harrowed 16,883 hectares; harvested 31,796; restored to cultivation 66,985; and carried out threshing representing 2,280 working days. Moreover, the Ministry of Liberated Regions furnished farmers with 462 tractors; 15,400 ploughs; 28,733 harrows; 14,935 mowers; 11,680 reapers and binders; 11,353 cream separators and churns; 25,150 carts; 56,638 sets of harness; and 185,865 other machines.

At the same time the work of re-forming the live stock of the country was carried on, and these regions were given 125,360 cattle; 133,455 sheep and goats; 197,326 horses, donkeys and mules. It should be noted that Germany did not do her part in reconstituting French live stock, and only delivered 65,560 cattle, 110,455 sheep and goats, and 31,926 horses, donkeys and mules; whereas her theft amounted respectively to 523,000, 469,000 and 367,000.

Industrially, with the assistance of the Treasury, much was done to repair war losses in the 15 months which followed the Armistice. By the end of 1920 80% of the industrial concerns were in full working order, and 26% were partly at work. As was to be expected, it was the big establishments which first resumed their activities. It is in comparing the number of people employed industrially in 1914 and on Dec. 31 1920 that the best idea of the situation of industry in the devastated regions can be obtained. In 1914 there were 791,000 people employed in the works, and the corresponding figure for the end of 1920 was 365,450, of whom 77,451 were directly employed in the work of restoration. An immense amount of work was done in reconstituting the limits of communes and of private property, the deeds and plans of which had disappeared.

At the outset of any consideration of the financial effort which this work entailed, it should be recalled that on April 17 1919 a law was passed declaring the principle that the damage suffered by the invaded districts was a charge upon the whole country. The legislature, interpreting the wishes of the country, considered that it was the nation's duty to restore the martyred provinces and to accept all their responsibilities resulting from devastation, even before any indemnity had been received from the enemy. Considerable capital was therefore necessary. By March 31 1921 the sum of 15,818,820,812 francs 45 centimes had been advanced to the liberated regions. Taking into account relief, 1,078,994,000 francs, and sums expended on works and purchases, 4,734,492,155 francs, the various expenses and expenditures of the departments for industrial and agricultural restoration, the moneys allotted to the rebuilding of devastated France amounted on March 31 1921 to 28,548,759,000 francs. In this figure the cost of railway reconstruction necessitated by acts of war has not been taken into account. It should be noted that the cost of administration had been low, not exceeding 2·17 per cent. (M. Pa.)

## French Colonies

The colonial domain of France, including colonies, protectorates, and countries for which France has a mandate, covers an area of 10,426,000 sq. km., an area nearly 20 times greater than that of France. The pop. numbers 55,000,000, nearly one and a half times that of France. The general trade of this colonial empire amounted in 1919 to over 7,000 million francs. In 1918 the figure was about 5,000 million francs. In 1913, the last normal year before war, it only amounted to 3,250 million francs. Exports and imports practically balanced each other. Although these figures appear small when compared with those of the British Empire, the French colonial empire is the second largest in the world, and its building-up is one of the best achievements of the Third Republic. The chief characteristic of these possessions is their variety. It is true that these colonies lie almost entirely in temperate or hot countries. Islands as well as vast continental stretches go to form this empire, which includes one of the greatest deserts of the world, the Sahara, as well as some of the greatest rivers, the Congo, the Niger and the Mekong. There are towering mountains, immense forests, and extremely fertile plantations. The produce of these colonies is also varied. It includes rice, sugar, wood, cotton, phosphates, cereals in great abundance, coal (but only in Indo-China), and metals of every kind. From the ethnical point of view its races include such different types as the Arab and the Berber, the Annamite, and the Congolese and Sudanese negroes. Although dotted over four continents, Africa, Asia, America and Oceania, it consists mainly of two big groups, one in Asia and the other in Africa. It is this latter portion of French colonial possessions which is by far the most important and the most full of promise. The French African empire, leaving Madagascar out of account, stretches in one unbroken sweep from Algiers to Brazzaville, and from Dakar to Abesher. It is formed by three great geographical unities: northern Africa, western and equatorial Africa, which encircles the Sahara and join at the central point of Lake Chad, with coast-line on the Mediterranean and the Atlantic. The great advantage of these possessions is their territorial continuity, and that some day a trans-Saharan railway will be able to run from Algiers to Brazzaville without leaving French territory. The gem of all the French colonies is N. Africa—Algiers, Tunis and Morocco. There three great advantages exist; the climate is temperate, the country is suitable for colonization by the French and all the other Mediterranean peoples, who acclimatize themselves as if they were in their mother-country, and, above all, these colonies are close to France. This situation is unique, and renders the colonies ten times more valuable. Such are the general characteristics of the French colonial empire. It was only during the war that France realized how valuable it was to her. The colonies were drawn on for material resources, and in particular for troops. Soldiers came into field against Germany in hundreds of thousands from the French colonies. All that could be obtained from these dominions has not yet been so drawn. French colonial policy is open to many reproaches, especially from an economic point of view. The exploitation of these countries has not been

pushed forward with enough energy, nor, more important still, with the necessary method. It has been carried on without a general programme, without stability of purpose, by improvisations, by little jerks, a system which has led to failures and, which is worse, to delays. M. Albert Sarraut, Minister for the Colonies in 1921, drew up a list of the great public works which had to be carried through in the colonies. In this programme he has applied the most recent doctrines of industrial organization, in particular the principle of division of labour, by which each colony will have to cease frittering away its efforts, and will have to concentrate upon the production or the industry to which its soil, climate or native traditions are the most suited. This programme of works covers railways, roads, canals, ports, irrigation, and farming, and provides for an expenditure of about 4,000 million francs. The chief of these works are the extension of the port of Dakar, the completion of the Thies–Kayes railway line, and irrigation works in the valley of the Niger in French West Africa; the railway line from Brazzaville to the Atlantic, in French Equatorial Africa; the rebuilding of the central Cameroon line, and the extension of it as far as Yaunde; in Indo-China, harbour works at Saigon, Haiphong, Tourane, Kwangchow-Wan, the completion of the Vinh–Donghoi line, and the continuation of the line across Indo-China from Tourane to Saigon; harbour works at Madagascar and at Jibuti.

(M. R.*)

## Army

The French army of 1921 was essentially in a stage of transition between the army of the World War, which had grown out of the pre-war national army (*see* Army: *French*), and the army of the future, which had to be adapted to future needs.

*Demobilization.*—In spite of the inevitable difficulties, especially in providing employment, demobilization after the Armistice of 1918 was carried out smoothly. The army was demobilized in ten échelons, as shown in the tables below, the whole procedure being directed by a specially created Under-Secretariate of State for Demobilization. The demobilization of these échelons was carried out in two stages, separated by an interval (April 3 1919 to July 9 1919) due to the necessity of retaining with the colours a sufficient strength to enforce, until the signature of the Treaty of Versailles (June 28 1919), the observance by the enemy of the conditions imposed by the Armistice. The tables below show the progressive movements of demobilizable personnel towards the demobilization depôts, whence the men were dispatched to their homes. The great task of transporting the men was successfully carried out, the first six échelons by special trains, the last four by utilizing the leave-trains.

After Jan. 1919 no men of the 1906 or older classes had been sent to the armies as reënforcements.

*Movements to the Demobilization Depots.—1st Stage.*

After the demobilization of class 1917 there remained with the colours two classes—those of 1918 and 1919, the latter having been called to the colours prematurely. The general mobilization of the army ceased on Oct. 23 1919, when hostilities were officially declared to be at an end.

Men called to the colours during the war, of ranks from captain inclusive downwards, received a fixed gratuity of 250 francs, with an additional bonus of 15 francs for each month of embodied military service; for each month of such service spent actually at the front, this bonus was at the higher rate of 20 francs.

*The Army in 1921.*—The actual situation in Jan. 1921 may be summed up as follows. France had an army of 100,000 men on the Rhine for 15 years (six infantry and one cavalry divisions). The strength of troops under arms was 830,000 men, made up as follows:—French (including 10,000 in the colonies), 572,000; natives of N. Africa, 152,000; foreigners and natives of other colonies, 106,000. In the 572,000 French troops were included the 1919 class (226,700), the 1920 class (first contingent, called up April 1920, 166,200; second contingent called up Oct. 1920, 83,000); voluntarily enlisted (45,500); voluntarily reënlisted and commissioned (40,000), and those in the colonies (10,000).

The new army laws of Dec. 1920 to May 1921 would take full effect on Oct. 1 1923. Until that date the army was to be gradually reorganized in accordance with these laws.

The organization of the nation in arms rests on universal, obligatory, equal and personal service. It is based on the principles of the inviolability of the military frontiers (which, for 15 years, include the Rhine), and of preparation for an administrative, industrial, and agricultural mobilization of the country.

The peace strength of the army is intended to be such as will secure for the nation the necessary time for the mobilization and concentration of its reserves, and for the organization of the entire productive forces of the country. The army in peace is further a school of instruction for the nation in arms, and a vast well, producing instructed reserves. The national army of 1914 had given place to the conception of the mobilized nation; the new army laws were directed to provide for the uncertain conditions of the transition period, in which the problem to be faced was not so much to meet and overcome foreign aggression as to be ready to maintain, by force if necessary, the conditions secured by the Treaty of Versailles.

The active army is recruited by contingents called to the colours each half year, and by voluntary engagements and reëngagements. Every Frenchman who is physically fit is obliged to serve 1½ years in the active army, 18½ years in the active army reserve, and 10 years in the territorial army. Time in excess of 1½ years spent in the active army, on voluntary engagement or reëngagement, is deducted from the period to be spent in the active army reserve. In peace-time only Frenchmen or naturalized Frenchmen may be enrolled, but foreigners declaring themselves without nationality may serve their time in one of the "*régiments étrangers.*" In time of war, the Minister of War is entitled to create corps of veterans by voluntary enlistment of men who have completed their full military service.

Soldiers of all arms are debarred from voting while serving with their unit. Each year returns are made, in every commune, of the young men reaching the age of 19 in that year. The classes are incorporated in two contingents. The first contingent, formed in April of the year following that in which the age of 19 was attained, comprises all those born before July 1 in the birth year of the class. The second contingent, formed in Oct. of the year following that in which the age of 19 was attained, comprises all those born after June 30 in the birth year of the class. Thus, the April contingent of the class 1923 would contain men

born in 1903, before July 1; the Oct. contingent of the same class, those born in 1903 after June 30. Two brothers of the same class need not serve together—the younger being put back till his brother's 18 months' service is completed. Young men passing through the military schools in order to become regular officers contract an engagement for the period spent at such school *plus* six years from the date of their passing out. In case of emergency, a contingent that has completed its 18 months' service may be retained with the colours, and men in the first two years of their period in the active army reserve may be recalled to the colours. The above conditions hold good for Algeria, Tunisia and Morocco; and, with certain reservations, for all other French colonies and protectorates.

The principles governing the allocation, in peace-time, of each class's effectives to the different arms and services are the proportion of losses anticipated for each arm in war and the special class of men demanded by the conditions inherent in different arms and services. An increase in the numbers of native troops and the voluntary enlistments for technical troops are the main factors that make it possible to maintain the requisite strength with the reduced period of 1½ years' service in the active army.

The arms are five: infantry, cavalry, artillery, engineers and air forces. *Chars-de-combat* are classified under infantry, and the transport service under artillery.

Native regiments are increased, as compared with the army of 1912, as follows:—infantry regiments, from 4 to 42; cavalry regiments, from 4 to 14; artillery regiments, from 4 to 6.

The active army consists of:—(1) Personnel of the five arms; (2) the corps of general officers and general army services (staff services and "*Corps du Contrôle de l'Administration de l'Armée*"); (3) special staffs and services, *e.g.* supply, health, veterinary, interpreters, recruiting, remounts, research of various kinds, physical training, military justice, military schools, and construction services; (4) the gendarmerie.

The number of infantry divisions in France and the occupied European countries is laid down as 32 (to which must be added a mixed detachment of police for the Sarre territory and Corps of Occupation of Constantinople), the number of cavalry divisions as 5, and of air divisions as 2.

The grouping of troops for colonies, protectorates, and territories occupied under mandate from the League of Nations, is subject to the exigencies of the local political and military considerations of the moment. The allotting of troops of all arms by theatres of operations is fixed by decree as occasion arises.

The old system of basing the organization of army corps on districts (*régions territoriales*) was no longer feasible, owing to the increase or creation of technical troops whose rôle was not conformable to territorial districts, and to the necessity, inherent in modern war, of creating in war-time great new units not foreseen in peace-time. Moreover, the independent army organized on a territorial framework was incompatible with the conception of the economical mobilization of the entire forces of the nation. The "*Projet de loi sur l'organisation générale de l'armée*," dated Jan. 18 1921, made the territorial organization and the organization of the formations of the army independent of one another. The active army, with its reserve, would, under this law, consist of the 20 youngest classes. The territorials would not, properly speaking, be an army, but a mass of formations, composed of the 10 oldest classes, organized for military work behind the army or at home. The 21 *régions territoriales* (20 excluding Algiers) created by the laws of 1873, 1897 and 1913, were maintained. Of the three military governments (Paris, Lyons, and Metz and Strassburg) created by the laws of 1875 and 1919, that of Lyons was suppressed. The army was to be grouped in higher formations (divisions and non-divisional formations). Thus, the *formation d'organisation* could be changed, and would be commanded, without reference to the "regional organization." Thus, in war-time, there would be *no reserve formations*, but one great "mobilized active army," consisting of as many "higher formations" as could be formed and maintained out of the two classes of the active army and the 18 classes of the active army reserve. The active army in peace-time is thus seen to consist of a number of divisions and non-divisional formations, which, for peace purposes, are under the general control of the *général de division* commanding the *région* in which the headquarters of the division or formation is situated. The active army in war consists of these divisions and non-divisional formations, increased, if necessary, up to the limits imposed by the resources of the 20 youngest classes. These formations can be grouped, as the situation demands, in army corps, armies, and groups of armies. (M. K. W.)

### Navy

During the World War certain changes were made in the distribution of the French fleet, and in the purposes for which its stations were used. Thus, the trading station of the Ocean became the base of reserve cruisers. The trading station of the Mediterranean became one of the naval bases and a port for reserve cruisers; the Toulon naval munition works was devoted to the production of shells for the army; the electricians' station of the Mediterranean became a base for general fleet purposes, just as the torpedo school at Brest was converted into a torpedo base. The schools at Brest and Toulon for cadets, both of the executive and engineer classes, were abolished; St. Raphael became the main naval aviation school, and Brest and Bandol the chief listening schools.

The whole naval building and distribution programme was profoundly altered by the war. From a building point of view, army mobilization put an end to the activities of nearly every French shipyard. Even armour plate ceased to be manufactured at Le Creusot, because the men engaged in that industry had been called to the colours. This was remedied to a certain extent, but from a general point of view it may be said that the industrial activity of public and private naval armament establishments was closed down, except in those cases where the plant and staff could usefully be employed in filling up the gaps of the industrial equipment of the country for army purposes.

The main task of the French navy during the war was in the Mediterranean, the Channel, and at the Dardanelles. Its losses were 166 vessels, of which 117 were due to enemy action and 49 were the result of collision and other marine casualties. The vessels lost by enemy action were: the battleships "Bouvet," "Suffren," "Gaulois" and "Danton"; four battle cruisers, "Gambetta," "Admiral Charner," "Kleber" and "Dupetit-Thouars"; one protected cruiser, "Chateaurenault"; 15 torpedo-boats; 10 submarines; two gunboats; one sloop; one transport; six auxiliary cruisers; 48 patrol-boats and mine-sweepers; 26 requisition transports; and one salvage vessel. Forty-one of these ships were lost by mine explosion; 58 were torpedoed by submarines; one, a submarine, was lost by aerial bombardment; the rest were sunk by shell-fire. Five torpedo boats, two submarines, two river gunboats, three vedettes, four submarine chasers, 25 patrol-boats and mine-sweepers, and two chartered transports were lost by collision, or by navigation accidents. The following vessels, which were damaged by shell-fire, torpedo or mine, were repaired: three battleships, one coastguard battleship, nine torpedo-boats, six patrol-boats and mine-sweepers, and one submarine. The losses in personnel, including those suffered by the marine brigade at the front, amounted to 10,896 killed, of whom 316 were officers. Those missing at sea amounted to 4,754, of whom 203 were officers.

When the Armistice negotiations began the French fleet comprised 1,296 craft on the active list. The majority, 874, was employed upon anti-submarine work. There were 735 vessels detailed for convoy, patrol and fishery protection duty. There were 139 submarine chasers, 192 mine-sweepers, and 70 vessels were engaged in war-pilotage. The fighting force of the fleet was formed by 117 battleships, cruisers, and destroyers, and 43 submarines. Although France quite naturally looked upon the navy as a subsidiary service during the war, thanks to the British fleet, she nevertheless provided 11% of the patrol-boats; 6% of the torpedo-boats; and 17% of the submarines in the Atlantic and the Channel.

The French navy, in Aug. 1914, only owned eight flying machines, and no more than 200 men were attached to the service of naval aviation. When the Armistice was signed the number of men employed in this service amounted to 11,000, and the navy had 1,264 air-planes or water-planes, of which 370 were in active service, and 257 dirigible and captive balloons. During the last year of the war the naval aeroplane service had over 70,000 flying hours and nearly 4,000,000 flying miles to its credit; and the lighter-than-air service had been in the air for over 12,000 hours, covering over 500,000 miles.

In 1921 the battle fleet of France consisted of three 1912 battleships, the "Bretagne," "Provence," and "Lorraine"; four battleships of the 1910–1 programme; four of the 1906 programme; five of the 1905 budget: the remainder were, in order, the "Courbet," "Jean-Bart," "France," "Paris"; "Diderot," "Condorcet," "Voltaire," "Vergniot"; "Justice," "Vérité," "Democratie," "Patrie" and "République." The 1912 battleships were of 23,500 tons, steaming 20 knots; the 1910–1, of 23,400 tons and the same speed; and the rest had a steaming capacity of about 19 knots.

Of battle cruisers, France had three of the 1907–8 programme of 14,000 tons; three of the 1904 budget of 12,500; four of the 1900 programme of 10,400 tons; two of 1900 of 9,500 tons; one of the 1901 programme of 7,700; one of the 1899 programme of 11,300 tons, and one of the 1895 programme of 5,350 tons. There were six protected cruisers, which might be regarded as obsolete; one old cruiser which had been converted into an aeroplane tender; and some 70 destroyers and torpedo-boats, most of them of ancient date. French submarines numbered 43; the Peace Treaty had given to France a certain number of obsolete German units. (G. A.)

### The French Labour Movement

The most prominent feature in the contemporary French labour movement has been the check given to "Syndicalism," as represented by the *Confédération Générale du Travail* (C.G.T.). This body is peculiar inasmuch as it is quite independent of political parties. Its organization is somewhat complicated. The workers of any one trade—builders for instance—have their National Federation, which is constituted by delegates appointed by the various building trades syndicates, masons, carpenters, etc. The various federations—building trades, metal workers, railwaymen, etc.—each elect a delegate, and their delegates together form one section of the C.G.T. Another section is formed by delegates elected by regional groups of all syndicated workers without distinction of trades. The C.G.T. is thus a body formed by delegates of regional unions on one hand and of national trade federations on the other. It groups labour representatives nationally and regionally—vertically and horizontally. The men thus elected form the National Committee of the C.G.T. It meets every three months, lays down the broad lines of syndicalist policy and every two years appoints the administrative committee of the C.G.T.

It should be noted that all these various groups preserve their autonomy as regards action provided that they observe the general statutes of the C.G.T., the chief of which declares that the C.G.T. groups working-men without distinction of religious or philosophical opinions with the object of suppressing "wages and employers." Every two years the bureau of the C.G.T. has to give an account of its stewardship to the National Congress, at which every syndicate, no matter what the number of its members may be, has one vote.

Such was the organization in 1921. It changed but little in form during 1910–20, but one slight modification whereby provincial delegates were allowed to sit every three months on the National Committee considerably modified its operation after 1918. Up till then provincial organizations were always represented by Parisian "militants," usually extremist in tone. Fernand Pelloutier, Pouget and Griffuelhes were then the organizers of the C.G.T., by which they hoped to wean the syndicalist movement from the influence of the parliamentary Socialists who were in favour of accepting social reforms. Their aim was to bring about a syndicalist revolution, and, as preparation for this upheaval, to accustom the working classes to "direct action," "sabotage," "anti-militarism" and violence of every kind were weapons to be used.

This doctrine of 1910 was systematized by the syndicalist thinker Georges Sorel. All social reform was scorned by these revolutionary syndicalists as being nothing but an opiate administered to the working-classes. Thus the Workmen's Pensions bill (1910), which made contributions from employers and employed obligatory, was vigorously resisted by the C.G.T.

More moderate men, however, while they were in favour of the independence of the C.G.T. from socialism, opposed violence and supported reform and parliamentary action. For three months indeed, one of their number, Niel, held the post of general secretary of the organization after the failure of the postal and railway strikes of 1909–10. The revolutionaries, however, after storming the offices, drove him from power. Constant street disturbances, May Day riots, prosecutions for seditious anti-militarist propaganda, make up the history of the C.G.T. in the few years before 1914. The fact that it had not more than 300,000 subscribing adherents kept funds low—in accordance with the doctrine that revolutionary action can only be obtained by a vigorous minority. At Havre (1912) the independence of the C.G.T. from all political parties was again affirmed, but the C.G.T., which declared that syndicalism was sufficient to itself, nevertheless desired to convince the world at large of this truth. International syndicalism met with but little success, for the German syndicalists would not look at plans for a general strike in the event of war.

*C.G.T. and War.*—Resolutions had been frequently adopted at C.G.T. congresses making it the duty of every member of the C.G.T. to reply to mobilization orders by proclaiming a general strike. But when mobilization was ordered on Aug. 1 1914, national enthusiasm swept away even the recollection of such decisions. French syndicalists had many reasons for suspecting the sincerity of German revolutionary pacifism, and on Aug. 3 Jouhaux, secretary general of the C.G.T., speaking at the funeral of Jaurès, preached the duty of national defence. This lead was accepted so loyally that none of the contemplated arrests of anti-militarist agitators was effected. Throughout the war Jouhaux and his followers observed the "*union sacrée*" and indeed began to perceive that capital and labour might have interests in common. A noteworthy sign of this new feeling was the presence of Jouhaux at the 1917 banquet of the federation of French manufacturers and merchants.

A small group of men inside the organization looked upon Jouhaux as a "traitor" to the cause, and sought at Kienthal and Zimmerwald the means of bringing the war to an end, at the same time encouraging agitation in this sense among workmen in France. By 1917 large numbers of men had been sent back from the front to work in munition factories. Considerable discontent prevailed, which led to grave strikes especially in the Loire. The settlement of those disputes in no way disarmed the extremists, who were dazzled by the Russian Revolution. The split widened with time, and peace in no way improved matters. The strength of the C.G.T. was officially recognized by the appointment of Jouhaux to be a delegate of the French Government for the consideration of Labour questions at the Peace Conference in Paris. He subsequently became a member of the International Labour Bureau, the director of which, Socialist deputy Albert Thomas, while Minister of Munitions, had exerted great influence over labour.

Syndicalism flourished at this period. Its effectives had risen from 300,000 before the war to 2,000,000. One cause of this is to be found in the special treatment given to labour during Albert Thomas' term of office. Skilled men obtained exemption from the army with greater ease than before, wages had been greatly increased, and in negotiations the C.G.T. had become an officially recognized body, of which it was almost necessary to be a member. M. Jouhaux, its head, played an important part in Government councils, and M. Clemenceau himself at one time wanted to offer him office as Minister of Labour. C.G.T. doctrine had

in fact ceased to be a bogey. It still kept all its pre-war revolutionary formulae, but they had ceased to have any real meaning. During the war labour had been given many opportunities of studying the intricate mechanism of State affairs and of appreciating that Karl Marx had perhaps not said the last word upon modern economic problems. Many of them began to ask themselves whether they were after all able with their experience and with existing labour organizations to take over, as they desired and hoped to do, the responsibility of national production. Without, therefore, throwing overboard their theoretical conceptions, they nevertheless began to see the need of caution and further knowledge if they were not to fall when their time came to take power. Moreover, they clearly saw that war had left the country in such a condition that ill-considered action might lead to general chaos. Proudhon thus took Marx's place. While Jouhaux in 1919 declared that revolution was "the workshop taking the place of Government," Merrheim maintained that the only chance of success for syndicalist ideas lay in carefully prepared economic revolution, and began to fight Bolshevism. This doctrine aroused the sympathy of the professional classes, who came to the assistance of the C.G.T. when it formed an Economic Labour Council for the elaboration of its new programme. It was composed of civil servants, engineers, technical experts, men of science and coöperative workers. Civil servants who had obtained the right of forming a union of their own adhered to the C.G.T. The Eight Hours' Day bill became law, and Clemenceau, speaking as prime minister to the C.G.T. leaders, told them that the time had come to take their place in Government. The movement was at its topmost height.

While the leaders were thus daily increasing their prestige and influence in the country at large their position with the rank and file was being equally steadily undermined by the "extremist" opposition. Strike followed upon strike, and wage demands continued to soar. The revolutionary elements, who reproached the C.G.T. with having failed to launch a revolution during the war or during demobilization, got ready for open warfare. Extremists organized demonstrations on May 1 1919, which ended in fatal rioting. Jouhaux at once gave ground to the revolutionaries, and resigned from his post at the Peace Conference. A general strike, prepared for July 21, failed owing to the firmness of the Government. The C.G.T. then retired into splendid isolation. Its chief concern was the elaboration of schemes for the nationalization of railways, mines and motive power. In April 1920 the extremists, with the growing support of Socialist Communists, captured control of the railwaymen's union and proclaimed a strike—the second within three months. Instead of disavowing it the C.G.T., in support of the movement, decreed a number of successive strikes, calling out miners, transport workers, dockers and seamen. Society, however, stood firm and the C.G.T. met with disaster. Within a few weeks it lost two-thirds of its members. The leaders who had failed to withstand pressure from the extremists were held by them to be responsible for the débâcle, and in every meeting they were assailed with the utmost ferocity. The Orleans Congress (held in Sept. 1920) was in its way a defeat for the extreme Left, whose leaders were in gaol awaiting their acquittal on a charge of having conspired against the State. That defeat was more apparent than it was real, for the Bolshevist Left forced the moderates to accept in the very heart of the C.G.T. the formation of revolutionary syndicalist committees whose avowed object it was to get rid of the official leaders, to resume pre-war doctrines and to link up with Moscow.

In 1920 the C.G.T. tried, but without complete success, to exclude all those who adhered to the Bolshevists. Its members then were about 600,000. It was still, however, linked up with the reformed International Federation of Syndicates, and its chief concern was to devise a plan whereby German labour could collaborate in restoring the devastated regions.

*Socialist Party.*—Although the C.G.T. always theoretically declared itself to be quite independent from the Socialist movement, concerted action was frequent before the war and machinery was created to coördinate their action.

The Socialist party in 1920 had about 60,000 members and was composed of many conflicting schools. Even after the process of unification differences between the sects were frequent, and all the tact and authority of Jaurès were needed to preserve the semblance of harmony. The organization of the party had at its base local sections grouped into departmental federations, the delegates from which formed the National Council. This body appoints an executive committee. The Socialist parliamentary group, which always kept rather aloof from the party organization itself, was represented at the annual Congress.

The funds of the Unified Socialists were obtained from 50-c. subscriptions from all adherents and an annual subscription of 3,000 fr. from deputies. The official organ was *l'Humanité*.

Before the war there were three tendencies clearly defined within the party. There were the followers of Jules Guesde, who believed in the utility of social reforms and in the possibility of acquiring power by constitutional means. They were opposed to Socialist acceptance of office in a "bourgeois" ministry. They rejected the general strike, anti-clericalism and anti-patriotism, and fought against any understanding with other parties and notably against the *bloc* of the Left which controlled national policy during the Combes and Waldeck-Rousseau Ministries. They were austere doctrinaires and pure Marxists. Thus Guesde refused to vote for workmen's pensions.

Jaurès and his followers were more broad-minded and would have accepted ministerial office. They believed in social reform, were ardent in the fight against the Church, and advocated union with other groups of the Left. Gustave Hervé (who subsequently has become reconciled to patriotism) in those days led the extremists. He preached rebellion in the time of war and scoffed at all the theories of Karl Marx. These three schools clashed at every National Congress but the conciliatory skill of Jaurès always produced a resolution so ambiguous in its phraseology as to be adopted with unanimity. Since syndicalism had emancipated itself from the Socialist party the action of this latter was almost entirely parliamentary. Its policy was simple: Abroad an understanding with Germany, Alsace-Lorraine being definitely abandoned, no colonial conquests, evacuation of Morocco or, at most, peaceful penetration of that country; at home social reforms, State monopolies, taxes on capital and income, reduction of term of military service and adoption of militia system.

Jaurès leavened all this dough with his great eloquence. Guesde spoke rarely and always bitterly. Marcel Sembat showed with wit, in his book *Faites un Roi, Sinon Faites la Paix*, that socialism was the only safeguard against war.

On July 31 1914 Jaurès was assassinated by a fanatic, Raoul Villain (afterwards acquitted). Jaurès had just returned from Brussels where the German Socialists Müller and Scheidemann had declared that their followers would not vote German war credits. This promise was not kept, and the French Socialist party also voted war credits on Aug. 4 1914.

In 1915 the first signs of dissension in the Socialist ranks became visible. Up till then the participation of Jules Guesde, Sembat and Albert Thomas in the Ministry had been accepted without opposition by the party. This changed, however, when the idea of a compromise peace first made a small number of converts among Socialist deputies. In 1916 this section grew in influence. It created its organ *Le Populaire*, and had as its leaders Paul Faure and Jean Longuet. Still further advanced along the road to compromise were the extremists Alexandre Blanc and Raffin-Dugens, who were linked up with revolutionary syndicalists and took part in the manœuvres for peace at Zimmerwald and Kienthal. The position did not change much until the Russian Revolution. While Albert Thomas, Marcel Cachin and Ernest Lafont were sent to Russia in the hope of preserving the military alliance, the extremists and Longuet's followers clamoured for passports for their delegates to the proposed Stockholm Socialist Peace Congress.

The Bolshevist Revolution had two effects upon the French Socialist party. It widened the gap between the patriotic "Majority" section and those who espoused the cause of Lenin, and

it aroused public opinion against "defeatist" Socialism. Meanwhile Longuet and his followers defeated Renaudel, and the patriotic section and all Socialist connexion with the Government was broken. At the Congress of 1920 a number of deputies were excluded. They had refused during the general elections to fight in the same lists as Jacques Sadoul, a notorious French officer who was playing a big Bolshevist part in Russia, and who had been sentenced to death *in contumaciam* by French court-martial. This was the first scission. The extremists were growing in numbers, and it was soon the turn of Longuet and his followers. At the Tours Congress adhesion to the Soviet was voted by a large majority and the moderates were expelled.

In 1921 there remained three parties amid the ruins of former Socialist unity. The Communist party, having *l'Humanité* and the *Internationale* as its organs, belonged to the Soviet or Third International. Its leaders were Marcel Cachin, Frossard, Daniel Renoult, Souvarin, Rappoport, Amedée Dunois and Victor Meric. Its organization was centralized, and its affairs were controlled by a central committee. Fourteen deputies represented it in the Chamber of Deputies, and its adherents numbered about 100,000.

The Socialist party had *Le Populaire* as its organ. It had about 50,000 members and 60 representatives in Parliament, among whom the chief were Sembat, Guesde, Basly, Leon Blum and Paul Boncour. The French Socialist party, the third portion, was of minor importance. (R. R.*)

### Political History

The political history of France from 1909 until 1913 was that of a slow awakening of the country to the real meaning of German foreign policy. One danger signal was given in 1905 with the Casablanca incident; 1911 furnished another warning when the German gun-boat "Panther" appeared off the Moroccan port of Agadir. In 1913 the new German army law and special taxation for military purposes made the menace even more clear. At the outset of this period, however, internal politics, rather than those of Europe, occupied attention. On July 20 1909, the Clemenceau Ministry was defeated on a personal question, arising from a remark made during a naval debate on M. Delcassé's foreign policy. Briand followed Clemenceau in office three days later.

*Briand Ministry.*—The new premier took the portfolio of the Interior, and had as his chief colleagues Barthou, Justice; Millerand, Public Works; Viviani, Labour; Cochery, Finance; Gen. Brun, War; Adml. Boué de la Peyrère, Marine. Briand, in his ministerial declaration, July 27, showed by concentrating on social reform (old age pensions, income tax, customs tariff, and reorganization of the civil service) that he hoped to be allowed to let the sleeping dog, Germany, lie, and to prosecute a liberal policy, both towards capital and labour at home. During the recess which followed soon after his arrival in office he made an eloquent appeal (Oct. 10) at Périgueux, for the broader handling of political questions; for greater tolerance of opinion; for the destruction of parish-pump politics, and the cleansing of the "stagnant pools" of local interest in which national issues were all too frequently decided in a purely selfish sense. This speech, in which for the first time the policy of appeasement was openly preached by a Republican minister, made a great stir among public and Parliament, and aroused the fear among Socialist-Radicals and Socialists that too close a *rapprochement* with Conservatism was intended. Briand managed, after the assembly of Parliament, to allay these apprehensions.

Electoral reform, on the basis of proportional representation, was the first measure submitted to Parliament. The claims of this system had been advocated by an influential body of Parliamentarians, and their propaganda had made headway. Nevertheless, political leaders felt disinclined to take a leap in the dark, and Briand, having made the vote upon the matter one of confidence, the reform bill was rejected. After voting the State purchase of the Ouest railway, the House strengthened the protective system of 1892 by voting a general increase in the customs tariff—which was justified, or at any rate rendered necessary by the new fiscal burdens placed upon home industry by social legislation.

*Elections of 1910.*—Considerations of a large policy, rather than those of small concrete interests, dominated the elections of 1910. The Socialist-Radicals, having put through their drastic anti-clerical programme, had started upon equally sweeping schemes of social reform. Class appetites had been aroused, and every fresh act of social legislation led to an increase of the economic, social and political demands of Labour and its leaders. A series of strikes and disturbances, in 1907–8–9, some of them requiring to be quelled with great severity, coupled with the steady growth of taxation, had aroused the "black coat" population to the perils of demagogic competition. Radicals, never at any time very advanced, broke with their Socialist and Socialist-Radical associates, thus putting an end to the union of the Left which had waged the war against the Church.

While the extreme Left became more and more clamorous in its voicing of the demands of Labour, moderate Radicals sought to create a party of Order with which to stem the rising flood of taxation, and to curb the precocious proletarian ambition. Briand was the natural leader of such an effort. At Périgueux he had already drawn the attention of the country to the dangers of political and class intolerance. Speaking to his constituents at St. Chamond on April 15 he was more definite. After declaring that the spirit of party and anarchism were the worst enemies of society, he outlined a programme of government, the chief feature of which was a proposal intended to tame the Labour movement by giving to workmen's syndicates the rights and responsibilities of property and corporative status. These unions, under the influence of the extremist leaders of the Confédération Générale du Travail, were fast becoming dangerous centres of anarchy and hotbeds of class-hatred. Briand proposed to alter this by giving these unions full legal status. This was the concrete expression of his policy of appeasement.

The results of the elections were (the corresponding numbers in the previous Chamber are shown in brackets): Reactionaries (80) 71; Nationalists (16) 17; Progressives (60) 60; Left Republicans (82) 93; Radicals and Socialist-Radicals (269) 252; Independent Socialists (29) 30; Unified Socialists (55) 74. These results favoured Socialists at the expense of their Radical allies. Proportional representation was favoured by the great majority of the electorate, and became part of ministerial policy as laid down on June 1 1910 by the prime minister, Briand.

During the autumn vacation of that year a big railway strike gave Briand an opportunity of displaying statesmanlike courage, and of driving a further wedge in between the extreme and the moderate elements of the Left. The strike first broke out on the Nord railway, and spread to the Ouest and Midi systems. The Est and Paris–Lyons–Mediterranée lines were not greatly affected. There was a good deal of violence used by strikers, and *sabotage* was practised on a large scale. Briand faced the situation with great firmness, and used the army, not only in protecting property, but also in actual strike-breaking. All railway servants of military age were called to the colours, placed therefore under martial law, and left at their civilian posts, desertion of which became thus a military offence. Agitators among the men were drastically weeded out, and within a week a strike movement of a magnitude previously unknown in France had collapsed. The struggle had been carried on with great determination on both sides, and left much bitterness behind it. Briand's action in mobilizing strikers had naturally aroused the fury of the Socialists, who, on the reassembly of Parliament, attacked the legality of his action. The Ministry was kept in power thanks to the growing scission on the Left of the House, but a reconstruction of the Government was deemed advisable. Briand resigned on Nov. 2, and next day formed another Cabinet.

*Briand's Reconstructed Ministry.*—This new Government was composed exclusively of moderate Radicals. MM. Millerand and Viviani, who represented the Left wing in the Ministry, went out of office, and it was soon evident that Briand intended to lean more and more upon the Centre. He refused, in spite of very great pressure, to force the railway companies to reinstate the men dismissed as a result of the strike, and pressed forward his policy of compelling Labour organisations to confine their activi-

ties entirely to questions directly concerning their trade. Reconstructions seldom live long, and the enemies of the Ministry having failed to defeat Briand on social questions turned to the old and oft-tried weapon of anti-clericalism. MM. Malvy and Paul-Meunier, with an interpellation as to the spirit in which the Congregations Law was being observed, reduced the majority to six. Briand resigned on Feb. 27 1911, and M. Monis, a senator of advanced Radical views, succeeded him.

*Monis Ministry.*—M. Monis formed a purely Socialist-Radical Ministry. He himself took the Interior, and his chief colleagues were: Caillaux, Finance; Cruppi, Foreign Affairs; Berteaux, War; and Delcassé, Navy. Promise far outstripped performance with this collection of democratic talent. Faced with the concrete problems of office, the preachers of almost revolutionary social reform found but little to alter in the programme of their predecessors. They did, however, yield to Socialist pressure on the question of the reinstatement of railway strikers; but before the necessary legislation was passed, the Ministry fell. The same sterility marked the rest of the Government's social efforts; and its advanced Radicalism did not save it from serious disturbances arising out of the delimitation of the Champagne zone. In the Aube and the Marne the rioters were for a few days completely out of hand. The disorders were suppressed, and all attempt at fixing the Champagne zone was for the moment abandoned.

Monis, the premier, and Berteaux, Minister of War, were both victims of an accident at the start of an aeroplane race from Paris to Madrid on May 21. Berteaux was killed outright, but Monis, although seriously injured, remained in office, appointing Gen. Goiran to the vacant portfolio. The death of Berteaux, a man of great wealth and influence in Radical circles, was a great loss to an already weakened Cabinet. The situation, both at home and abroad, was full of difficulty. Socialist opposition to the Fez expedition (April–May) and difficulties with the administration of the Old Age Pensions bill would probably have been enough to bring about the collapse of the Ministry, which, however, fell on a question of the supreme command of the army in time of war. Parliament refused to give a vote of confidence to the Government, which declared that decisions as to the supreme command were its sole concern, and the Ministry resigned.

*Caillaux in Power.*—There was no real question of policy at issue. The Chamber had tired of the ineffectual mediocrity of M. Monis, and required more brilliant leadership. This was provided by M. Joseph Caillaux, who, on becoming prime minister, went from Finance to the Interior. M. Klotz became Minister of Finance, Cruppi Minister of Justice, and de Selves Minister of Foreign Affairs. Delcassé remained at the Navy, and Messimy took the War Office. This Ministry, by its mistakes, made a permanent mark upon the world's history. Its members were full of professed social and fiscal ambitions, which found their only manifestation in pettifogging party practice. From the point of view of internal politics it represented many of the worst influences of bigoted Radical tyranny, and in home affairs it was quickly discredited. Abroad its policy was well-nigh disastrous, and by its weakness, and by the tortuous secret diplomacy of Caillaux towards Germany, it very nearly plunged Europe into war.

*Agadir.*—Foreign affairs very soon absorbed the whole attention of both Parliament and public. Negotiations which had been in progress for some time with Germany over Morocco were given a definitely threatening aspect by the arrival of the German gun-boat "Panther" at the undeveloped port Agadir. Caillaux, who had always believed in the possibility of conciliation with Germany, conducted secret negotiations with Berlin without consulting the Cabinet, and without indeed informing his own Minister for Foreign Affairs of what was on foot. Throughout the summer European diplomacy was thereby plunged into the darkest bewilderment, and statesmen in more than one capital, unaware of Caillaux's underground conversations, were speaking and acting at cross-purposes with each other. It was impossible to maintain complete secrecy. M. Clemenceau among others became aware that something was going on, and public dislike of the trend of events led to an outburst of national feeling in September. Although the agreement of Nov. 4 1911, which resulted from official negotiations with Germany, was ratified by Parliament, the Cabinet, and its head in particular, had so lost in influence that the resignation of M. de Selves on Jan. 9 1912 brought about the collapse of the Government the next day. Caillaux's negotiations with Germany subsequently formed the subject of special parliamentary inquiry. The sordidness of the whole story and the light-hearted way in which Caillaux had played fast and loose with the honour of France and her friendship with Great Britain thoroughly disgusted the country, which had already shown many signs of discontent with the rule of narrow-minded Radical mediocrity even under a premier of undoubtedly brilliant talent. A recoil from Caillautism was inevitable.

*Poincaré in Power.*—Raymond Poincaré undertook the task of giving to the country the "national" Cabinet it desired. Three former prime ministers took office in his Government, the kernel of which was formed by Poincaré, Foreign Affairs; Klotz, Finance; Léon Bourgeois, Labour; Millerand, War; Delcassé, Navy; and Briand, Justice. Foreign affairs remained the chief preoccupation. The acute point of crisis with Germany was past, but the whole European situation was unstable, and called for the closest watchfulness. In home affairs, electoral reform took up the greater part of Parliament's attention. Vigorous action was taken against anti-militarist and revolutionary propaganda.

*Presidential Election.*—M. Fallières' term of the presidency of the Republic came to an end at the beginning of 1913. There were two candidates for the succession, Poincaré and Pams. Poincaré rallied to his support a great weight of feeling outside Parliament, whilst inside both the Senate and the Chamber of Deputies he had behind him the bulk of the Moderate Republican votes, and nearly all the Conservative elements. Clemenceau, alarmed by the almost reactionary nature of Poincaré's candidature, led the campaign on behalf of Pams, a Radical Republican of classic mediocrity, with such fire as to secure his adoption as Republican candidate in the party caucus meeting on the eve of Versailles. Poincaré, however, refused to withdraw his candidature, in spite of all the appeals made to him by Radical stalwarts to observe party discipline. The second ballot at the National Assembly, held at Versailles on Jan. 17 1913, showed that he had accurately estimated the general opinion of Parliament. He received 483 votes, his opponent Pams only obtaining 296. This result, while constituting a victory for Conservatism, was also a sign that people, alarmed by the portents in the international sky, wished to have a strong man at the head of the republic, and one capable of playing his own part in the relations of the republic with foreign Powers. Before Poincaré was installed at the Élysée (Feb. 18 1913), his successor as prime minister, Briand, was faced by the need to meet the growth in the military strength of Germany, which could not be left unchallenged.

*Briand's New Ministry.*—On Feb. 27 a first step was made towards this end, when a bill was tabled in the Chamber of Deputies, opening an extraordinary military credit of £20,000,000 for war material. On March 6, M. Étienne, Minister of War, brought in a bill raising the period of obligatory military service from two to three years. Before the bill could be proceeded with the Briand Ministry came to grief in the Senate, and, after an adverse vote of 33 on proportional representation, Briand resigned on March 18, having been in office for 56 days. The Electoral Reform bill was among the fixtures which Briand took over from Poincaré. It provided for proportional representation by means of the electoral quotient. The bill had been passed by the Chamber of Deputies, where Socialist support rendered Radical opposition ineffectual. In the Senate, however, the Radical *bloc* remained firm. Clemenceau saw in the bill an excellent opportunity of scoring against President Poincaré, who was a firm supporter of the measure. Moreover, he, with many other orthodox Radicals, was alarmed by the somewhat chauvinistic manner in which Poincaré's return to the Presidency had been greeted by the reactionary party, and suspected, in proportional representation, a device to increase the power of the Right.

*Barthou's Government.*—The crisis brought about by the defeat of Briand on this point was fortunately of short duration, and, on March 21, M. Barthou was able to form a ministry. Its chief

concern was to carry on the policy of its predecessor, and to press forward with unabated determination the military proposals before Parliament. So bitter was the opposition to the Three Years' Service bill that Barthou experienced no difficulty whatever with regard to proportional representation, which almost imperceptibly dropped for the moment out of the realm of practical politics. The critics of the Three Years' Service bill were recruited from among the ranks of the Socialists and Socialist-Radicals. They did not deny that some answer to Germany was necessary; that something had to be done to increase the military efficiency of France; but they urged that the Government, in asking the country to accept another year of military service, was demanding a sacrifice which would not be in proportion to the results achieved. They argued that it would be both less costly and more effective to reform the whole conception of army organization on the general lines advocated by the Socialist leader Jaurès and to aim at the adoption of the Swiss militia system. The utmost concession the Opposition was willing to make was to agree to an increase of six months in the total service.

The hostility against the proposals of M. Barthou was not confined to politicians. Very active propaganda against them was carried on throughout the country by Communists and Anarchists, and by anti-militarist agitators belonging to the Confédération Générale du Travail. This activity for a time had serious effects upon army discipline, and in more than one provincial garrison mutinies broke out. Happily they were not of a grave nature, and prompt action by the Government in arresting the ringleaders, and in showing their dupes and the country the unpatriotic motives which inspired the agitation, soon put an end to the unrest in the army. Legislation calling for the heavy sacrifice of a further year's military service naturally could not be popular; but the military activity of Germany, and the tone of speakers on the other side of the Rhine, left France in no doubt as to what was in store. The country realized the necessity for the fresh effort asked of it. Barthou fought the bill through the Chamber with skill and courage. He had to contend with violent opposition from the Socialists, and with all the dilatory tactics the ingenuity of Radicals could devise. After 22 sittings had been spent in discussing counter-proposals, the House began the consideration of the Government bill on July 7, and, by 339 votes to 223, carried the essential clause. By the end of the summer the whole bill had become law, and the main task of the Barthou Ministry was at an end. Hostility towards the Ministry was in no way abated, and Caillaux led his followers to victory on Dec. 2, inflicting defeat by 290 votes to 265 on a vote authorizing a loan of £52,000,000, mainly for non-recurring military expenditure. The Finance Minister, M. Dumont, asked that fiscal immunity should be extended to the proposed new *Rente*, a request which, as Caillaux pointed out, would have cut at the root of any just income tax, since between one-tenth and one-twelfth of French wealth is invested in *Rente*.

*A Doumergue Cabinet.*—Attempts were made to solve the crisis which had arisen, without paying due regard to the claims of the Socialist-Radicals. Both M. Ribot and M. Jean Dupuy tried unsuccessfully as Moderate Republicans to enlist the support of Caillaux and his friends. In these circumstances M. Ribot advised the President of the republic that the new head of the Government would have to be chosen from among the Left. Recollections of the part played by Caillaux in Franco-German relations made it difficult for the leader of the Socialist-Radicals himself to take office as premier; and it was M. Doumergue who, after a week of negotiations, formed a Government on Dec. 8, composed almost exclusively of Socialist-Radicals. The Ministry was Gaston Doumergue, prime minister and Foreign Affairs; René Renoult, Interior; Bienvenu-Martin, Justice; Noulens, War; Monis, Marine; Caillaux, Finance; Viviani, Public Instruction; Malvy, Commerce; Fernand David, Public Works; Lebrun, Colonies; Raynaud, Agriculture; Metin, Labour; Under-Secretaries of State, Peret for the Interior, Maginot for War; and Jacquier for the Fine Arts.

Interest in the new Ministry was confined to its financial proposals, and its attitude towards the Three Years' Military Service law. It soon became apparent that, whatever ministers had said about the new law when in opposition, they had no intention of interfering with its working. The preceding Government's bill for the issue of perpetual *Rente* was withdrawn, and a policy of Radical finance was outlined, based upon the taxation of acquired wealth. As a matter of political fact the chief aim of MM. Doumergue and Caillaux was to stay in power long enough to give to the approaching general elections a pronounced Socialist-Radical flavour. The waning power as a battle-cry of anti-clericalism, the personal talents of Caillaux, the involved condition of the French budget, no less than the real unfairness of the incidence of taxation, made of Caillaux's financial plans the main plank of his party's fighting programme. In the forefront of those plans were taxes on income and on capital. Before the year was over the electoral campaign had begun.

*The Fédération des Gauches.*—Briand, in a speech to his constituents at St. Étienne, voiced again those arguments in favour of conciliation which he had put forward at Périgueux and at St. Chamond. He attacked the old Radical school for its desire to keep alive for its own political benefit all the old class and clerical feuds. He recalled Caillaux's secret dealings with Germany, and dwelt scathingly upon demagogic plutocrats, who raised the dagger above wealth with such ferocity of mien that it was difficult to say whether they intended to strike at riches or to defend them. Briand rallied to his standard a large number of moderate men belonging to all opinions, and for electioneering purposes they formed a fighting body known as the *Fédération des Gauches*. It had the support of men like Millerand, Barthou, Klotz and Ribot, and carried on a vigorous campaign throughout the country in favour of the Three Years' Service law, and in opposition to the proposed taxation of income. When the Chambers reassembled after the New Year recess, finance was still their main business. The Briandists sought in vain to shake the Government majority. The Lower House, after a month's debate, approved the fiscal proposals of the Government by a majority of 115. In the Senate, however, which, being more Radical in politics, was therefore more Conservative in economics, Caillaux had to make concessions and on minor points suffer defeat.

*Madame Caillaux.*—Opposition to Caillaux and his policy found its most virulent expression in the columns of the *Figaro*, where, day after day, were published documents affecting the personal and political honour of M. Caillaux, as well as of his wife. These attacks were brought to a tragic end on March 16 1914, when Madame Caillaux, having previously taken lessons in revolver-shooting, called upon the editor of the *Figaro*, Gaston Calmette, and fired five shots at him. He died a few hours afterwards. The publication of the documents in the *Figaro* sought to prove that Caillaux had, throughout his political career, taken advantage of his position as Minister of Finance to line his own pockets, and that in particular he had brought such pressure to bear upon the judicial authorities that a notorious financial swindler, Rochette, was enabled to abscond while awaiting his trial. This was the most serious charge brought against him as a public man. The *Figaro* had, however, also started the publication of some very intimate letters written by M. Caillaux to his second wife, the shooter of Calmette, while she was still his mistress. In these documents, public and private matters were discussed with cynical licence; and in one of the letters Caillaux boasted to his mistress that in the Senate he had, as Minister of Finance in the Waldeck-Rousseau Ministry, "smashed the income tax (his pet measure) while appearing to defend it." The sensation caused by Madame Caillaux's deed was great. Rioting between Radical and Royalist gangs broke out during Calmette's funeral, and for some days Paris was in one of her typically effervescent moods. This manifestation was controlled without much difficulty, but it was less easy to limit the political effect of the crime. Caillaux at once resigned office, but Monis, Minister of Marine, was also deeply involved, as having been the prime minister who ordered the Procurator-General to postpone the trial of Rochette, and thus made it possible for him to escape to Mexico. Monis remained to face the storm in Parliament, which appointed a committee of inquiry as the result of further revela-

tions made by Barthou. The findings of that committee, and the censure passed upon Monis and Caillaux, were approved by the House after stormy debate. The parliamentary session ended on April 4, and from that date to May 10, when the second ballots determined the composition of the new Chamber, politicians in vain tried to stir the electorate from its indifference. Even the Calmette murder, the Three Years' Service controversy, and the income tax aroused but few people from their apathy. None regretted the deceased Chamber, and few were sufficiently awake to the growing dangers in Europe to take much interest in the election of deputies who were destined to form the French Lower Chamber throughout the war.

*Elections of 1914.*—A clear-cut issue between opposing parties is found but seldom in French elections, but the general tendency of the 1914 elections could be discerned. They were a fight between the Moderate Republican elements who elected Poincaré to the presidency of the republic, and who voted for the Three Years' Service bill and the Socialist-Radical and Unified Socialist groups. The political composition of the new Chamber was:—Unified Socialists, 102; Independent and Republican Socialists, 30; Unified Radicals, 136; Alliance Démocratique, 100; Independent Radicals and Left Republicans, 102; Progressists and Republican Federation, 54; Action Liberale, 34; Right, 36; Independents, 16. The only marked change was in the Socialist party. They made an electioneering pact with their neighbours, the Socialist-Radicals, by which they gained many seats in the first ballot; and where Catholics saw their candidate badly placed in the second ballot, and opposed to a Socialist and a Radical, their votes were transferred to the Socialist rather than to the anti-clerical Republican. Thanks to these two factors, as well as to a slight growth of Socialism in the country, the Socialist party made a net gain of 35 seats. The general effect of the elections was to strengthen the advanced Radical and Socialist *bloc* at the expense of the Briandists and the electors of M. Poincaré. This *bloc* of Socialists, Caillautists, Radicals and Independent Radicals numbered 226, and, although not an absolute majority in the House, Government without it was impossible.

*Viviani Prime Minister.*—In accordance with custom, Doumergue resigned before Parliament reassembled on June 1. It was found exceedingly difficult to replace him. The ministerial crisis lasted a fortnight, and more than one ministerial combination came to grief on the Socialist-Radical refusal to subscribe to a programme which did not include an early return to two years' service, or at least a drastic modification of the Three Years' law. It was on this point that M. Viviani's first attempt failed. The President of the republic, who had openly declared his intention to safeguard the new military law, then tried to bring about a Cabinet free from Socialist-Radical influence. M. Ribot rashly undertook to form such a ministry. It was boycotted by the *bloc*, and did not live a full 24 hours. The Chamber refused, by a majority of 44, to give it a vote of confidence, after hearing the ministerial declaration of policy. During the debate which led to this division advanced Radicals gave clear proof of their determination to reject any Government which was not in its essence recruited from their ranks. These circumstances led M. Poincaré again to summon Viviani, who, after this demonstration of Radical strength, and in view of the necessity of closing rapidly a ministerial crisis which had already lasted too long, found no difficulty in forming a ministry, and in finding a formula with regard to the Military Service law which, by its ambiguity, was acceptable to all save the extreme Left. It was composed as follows:—René Viviani, prime minister and Foreign Affairs; Bienvenu-Martin, Justice; Malvy, Interior; Noulens, Finance; Messimy, War; Gauthier, Marine; Augagneur, Public Instruction; René Renoult, Public Works; Gaston Thompson, Commerce, and Posts and Telegraphs; Fernand David, Agriculture; Raynaud, Colonies; Colyba, Labour; and, as Under-Secretaries, Abel Ferry, Foreign Affairs; Dalimier, Fine Arts; Lauraine, War; Jacquier, Interior; Ajam, Mercantile Marine.

During the debate upon the ministerial declaration policy, the premier strengthened those passages in the Government programme which dealt with the Military Service law. He gave some content to critics of that measure by announcing the Government's intention to introduce a number of bills providing for the military training of the young, and for the better utilisation of reserves, but was firm in saying that until that new legislation had shown its efficiency in practice, there could be no question of reducing the term of military service. This programme was far from satisfying the Socialists and some disgruntled Radicals, but they only mustered on the vote of confidence which ended the debate 139 votes to 362. The ministerial crisis was thus ended, but, more important, an end had been put to the agitation for a repeal or revision of the Service law.

*Three Years' Service Law.*—All possibility of tinkering with this law was abolished by the proceedings of the Senate on July 13, on which date the European outlook was overcast, when Charles Humbert made a sensational speech revealing the poverty of the French army in artillery and war material of every kind. Clemenceau supported him in his demand for an inquiry. Messimy, Minister of War, admitted that while the French field gun was superior to that of Germany, the French heavy artillery could not compete with that of her neighbour; that Germany was far ahead of France in the supply of engineering materials; that frontier fortresses were but poorly equipped; that bridge-building material was lacking; and that the French soldier would have practically but one pair of boots at his disposal on the day of mobilization. He pointed out that Germany had spent between 1900 and 1905 £28,000,000 on her army, as compared with French expenditure of £11,250,000. From 1906–10 Germany had spent £37,200,000, and France £19,000,000; from 1911–13 German military outlay had been £23,400,000 and French £16,500,000. Messimy maintained that the ground lost could be made good by 1919, and that the first step towards doing that could be taken by the Senate in passing the military credits for £56,320,000 which were then before it. This Parliament did, before adjourning on July 15.

It is difficult to estimate to what extent the public revelation of French military unpreparedness made during this debate encouraged the Central European States in their bellicose designs. Certain it is that both from Berlin and from Vienna the French ambassadors reported to their Government that the proceedings in the Senate had had a deplorable effect upon public opinion, and had considerably strengthened the hearts of the jingo parties in both states. Although the French Foreign Office had in its archives despatches from more than one of its ambassadors warning it in the most urgent manner of the perilous condition of European affairs, or perhaps because it was deemed advisable to remind Germany of the solidity of the Franco-Russian alliance, the French President's visit to Russia was carried through according to programme. Poincaré left at midnight on July 15 1914, accompanied by the premier and Foreign Minister Viviani.

*Madame Caillaux's Trial.*—From the point of view of internal politics, it was undoubtedly desirable that the trial of Madame Caillaux for the assassination of Calmette should take place during the parliamentary recess, and while the Chief of State was abroad. Caillaux, who, in spite of the sensation caused by his wife's action, had again been returned to Parliament for Mamers, had lost no opportunity of giving to the whole *affaire* its full political flavour, and saw quite clearly that in court not only would his wife be on trial for her life, but he also and the whole of his policy and party would be arraigned. He subsidized newspapers and inspired campaigns, some of which were but thinly veiled threats of blackmail upon the President of the republic. He succeeded in making of his wife's trial the all-absorbing question of the day. The assassination of the Archduke Francis Ferdinand, the thunderclouds in the East, and revelations as to French unpreparedness, all failed to distract public attention from the Caillaux drama. The trial opened on July 20, and for a week France gave herself up to morbid contemplation of the rottenness of the social and political life of many of her leading men and women. The greatest lawyers of France were engaged in the case: Maître Ferdinand Labori for Madame Caillaux; and Maître Chenu for the Calmette family. Both defence and prosecution sought for mud with which to bespatter those con-

cerned in the case; and, whether a witness were a minister, an actor, a journalist, or a woman, mud was found in plenty. There was no questioning the facts that Madame Caillaux shot Calmette; that she purchased the revolver on her way to the *Figaro* office; that she had carefully learned how to use a revolver; and that she had left a note for her husband telling him that she meant to take justice into her own hands. Nevertheless, after an impassioned speech by Maître Labori, she was acquitted by the jury—a result due more to the nature of the questions left to the jury's decision by the judge, and to the dependence of the Bench upon the favour of ministers, than to any consideration of the rights and wrongs of the case. The Caillaux propaganda outside the court increased as the trial proceeded, and sought to give to the proceedings the appearance of a political trial in which Caillaux's political adversaries were trying to find in the homicidal impulses of his wife a weapon with which to kill their chief political opponent. Temper rose rapidly to fever-heat, and by the time the verdict was given war-fear and war-fever helped to send up the temperature of Caillaux's most ardent supporters, the Socialists and Syndicalists, and of his most bitter enemies, the Royalists. The boulevards were packed with struggling *Camelots du Roy*, and gangs of the *Jeunesse Républicaine*, whose contending battle-cries of *"Vive Caillaux!"* and *"Caillaux Assassin!"* mingled with *"À Berlin!"* and *"À bas la guerre!"*

*Outbreak of the World War.*—This local rowdyism in no way echoed the real feeling of the country, which saw with courage, but without any exultation or jingo fever, the approach of war. The President of the republic returned to Paris from his Russian visit on July 29, and was warmly cheered as he drove with Gen. Joffre to the Élysée. There was perhaps a significance even in the warmth of those cheers; but had the scuffling on the boulevards been due to really deep feeling for or against war, the murder of Jean Jaurès, the idolized leader of the Socialists, as he was dining in a Paris café on July 31, would inevitably have led to very serious rioting. He was shot down by a Paris student named Raoul Villain, whose mind had apparently become affected by the ferocity of Royalist attacks upon the People's Tribune. (Villain was not brought to trial until March 1919, when, to the astonishment of everybody, he was acquitted.) The body of Jaurès was carried by Socialist stalwarts along the boulevards to his home at Passy without there being any disturbance of order. The next morning France was placarded with a ministerial proclamation explaining the crime and identifying the Government with the feelings of horror and grief which it had aroused.

Mobilization orders were posted throughout the country on Aug. 1, and at the same time was issued a presidential proclamation explaining that, though mobilization did not of necessity mean war, it had become a necessary step in view of the bellicose actions of Germany. The proclamation appealed to the country to refrain from any emotional displays which might embarrass the last efforts of diplomacy to preserve peace. These exhortations to be calm seemed to be superfluous. Mobilization was carried out quietly even in the effervescent capital. Scenes of jingoism were rare, and their significance was slight. A few Germans were naturally hailed as spies and roughly handled and some German shops were smashed up. A true picture of the national attitude towards war is to be seen in the sitting of Parliament on Aug. 4, when a presidential message was read outlining the history of diplomatic negotiations and their failure to weaken or stay the warlike intentions of Germany. In both Houses members stood in complete silence during the reading of the address, but the concluding appeal *"Haut les cœurs, et vive la France!"* was followed by the singing of the *Marseillaise*. In this demonstration of patriotic unity, in the applause which marked the words, "We are no longer partisans here, we are all Frenchmen," Socialists and Monarchists joined with equal fervour.

*L'Union Sacrée.*—Thus was born the political truce, the *Union Sacrée*, which for the first two years of war enabled French Governments to continue in office without having to meet open attack. For the first two years of war this immunity against criticism had its good points. It gave greater stability to the country's affairs; the supreme command had the sense of continuity essential for the preparation of the offensives of a long war. The system had also its disadvantages, for it meant lack of control, and, since rigorous censorship was imposed, the stifling of all public opinion. At the very outset of the war changes were made in the Ministry. Viviani, so as to free himself for the general control of the Cabinet, gave the portfolio of Foreign Affairs to M. Doumergue; Augagneur became Minister of Marine, and Sarraut succeeded him at the Ministry of Public Instructions.

*Ministerial Changes.*—On the eve of the first battle of the Marne the Ministry was further strengthened, Viviani resigning on Aug. 26 and forming a new Government. The steady advance of the enemy, the disasters at Charleroi and Mons, and the prospect of battle at the very gates of the capital, called for the presence of stronger men. The most important change was that which put Millerand in the place of Messimy at the War Office. Delcassé returned to the post from which German arrogance had forced him years before—to the Foreign Office; Augagneur took the Navy, Ribot Finance; and, as a concrete sign of the *Union Sacrée*, Socialist deputies were authorized by the party for the first time to take office in a bourgeois Cabinet. Marcel Sembat, one of its wittiest leaders, became Minister of Public Works, and Jules Guesde, a Socialist veteran of uncompromising principles, joined the Ministry without portfolio. The label "National Defence" was fixed to this Cabinet, which was representative of nearly all political parties. Its first concern was the defence of Paris. The day this Ministry was formed Gen. Galliéni replaced Gen. Michel in the military governorship of the city. The appointment of such a resolute die-hard as Galliéni to this post was a clear indication that, if the worst came, Paris would be defended and fought for even through her streets. The impression made by this appointment upon the public, which knew nothing of the course of events at the front, or indeed realized how near the front was drawing, was heightened by the arrival of thousands of refugees, who streamed into the capital from the direction of Amiens and Compiègne.

*Departure for Bordeaux.*—The closing days of Aug. were marked by a great exodus of useless mouths. The Government endeavoured, in conditions of great difficulty, to evacuate as many people as possible from Paris, but was naturally hampered in so doing by the fear of causing anything like a general panic among the population. It was therefore unable to issue any proclamation, and what measures it took to encourage people who were not forced to remain in Paris to leave for the provinces had to be carried out more or less *sub rosa*. Its own departure to Bordeaux took place by stealth. The Government and the President of the republic were bluntly informed by the commander-in-chief, Joffre, that their presence in Paris during a battle which would decide the fate of the capital could only give to the army unnecessary preoccupations of a political nature, and that they would best serve national interests were they to betake themselves well out of the zone of operations. The President of the republic and the ministers left Auteuil station secretly on the night of Sept. 2, and it was not until the following day that the country was told of this momentous step, in a proclamation which appealed to it "to fight and to endure," and which called upon members of Parliament to rally around the Government at Bordeaux, so as to form with it "a rampart of national unity." The Government was naturally followed to Bordeaux by all the embassies and legations, with the exception of those of the United States, Spain, Denmark and Norway, which were charged with the interests of one or other of the belligerent Powers. For days the roads to Bordeaux were encumbered with the heavy motor traffic of well-to-do refugees: the ordinary railway-travelling public had to put up with very great delays upon the line; the diplomatic train itself took over 24 hours to reach the temporary seat of the French Government. Most of the members of Parliament were prompt in their response to the appeal of the Government that they should go to Bordeaux. There was therefore not a little indignation when the Government almost immediately declared closed the session of Parliament which had been technically adjourned since Aug. 4. Discontent showed itself in a half-hearted attempt to prepare the Alhambra and Apollo

music-halls for a meeting of the two Chambers. No session, however, was held at Bordeaux. Most deputies realized that a resumption of political activity in Bordeaux, while the fate of Paris was in doubt, would be viewed unfavourably by the country. Parliamentarians, moreover, had more immediate duties to perform in their constituencies. Parisian deputies had naturally remained behind, and for a time assisted Gen. Galliéni in his task of preparing Paris for the fight. Their activities in Paris were such as to lead to some misapprehension, and the fear that there might arise some sort of double government in the country. Those apprehensions were dispelled after a visit paid by Briand to Paris. After the Marne the Government remained at Bordeaux, endeavouring to make good the many deficiencies in army equipment and training revealed in the opening stages of hostilities. Shell shortage was the chief difficulty, and Millerand also had to consider the terrible deficiencies of French army medical services. Motor ambulances were practically non-existent; wounded had been left for days untended and lying in the filth of cattle and horse trucks; the hospitals themselves were not sufficiently numerous; they were badly organized and lacked elementary equipment. It was upon this second point that criticism of the Government first became open. Clemenceau, whose daughter was nursing in one of the Bordeaux hospitals, defying the censorship, daily thundered against the rottenness of Millerand's medical services; and when his paper, *L'Homme Libre*, was suppressed, it reappeared as *L'Homme Enchaîné*.

All the chief organs of public opinion had followed the Government into exile from the capital, and those which were unable to find printing accommodation at Bordeaux spread themselves through the cities of the south. During this period, in spite of vigorous censorship, sufficient became known to Parliamentarians and to journalists to make it apparent that the complete immunity from criticism which the Government had enjoyed could not with public safety be maintained. The demand that the censorship be relaxed, and that Parliament should be summoned to meet once more, became insistent.

*Return to Paris.*—The solidification of the front along the trench positions of the Aisne and of Flanders made it possible for the public services to return to Paris, which they did during the month of December. On Dec. 22 1914 the prime minister, Viviani, addressed the Chamber of Deputies, which had not met since Aug. 4. Even vehement critics of Government realized that at this first meeting of the Chamber under war conditions but one feeling could be voiced—the national resolve to fight on to victory. Viviani, in language strikingly similar to that used by Mr. Asquith previously at the Guildhall, declared, "France, in accord with her Allies, will not lay down her arms until she has avenged outraged right, and regained for ever the provinces ravished from her by force, restored to heroic Belgium the fulness of her material prosperity and her political independence, and broken Prussian militarism." He made an eloquent appeal for the maintenance of national unity, saying, "In order to conquer, heroism on the front does not suffice. Union must prevail within our walls. Let us preserve the *union sacrée* intact. To-day, as yesterday and to-morrow, let us have but one battle-cry, 'Victory,' but one vision before our eyes, 'La Patrie,' and one ideal, 'Right.'"

*Parliamentary Criticism.*—By the end of 1914 all sections of French opinion had realized that the British had been right in predicting that the war would be long; and those behind the scenes became seriously alarmed at the lack of preparation for a long-drawn-out struggle, the lack of a comprehensive and far-sighted programme of munitions and finance. Parliament had patriotically surrendered all its powers of criticism and control to the executive Government during the critical opening months of hostilities. Early in 1915 deputies, realizing that the only chance of victory lay in proper organization of the whole people for war, and that the trench line was a sufficient barrier behind which to accomplish this work, claimed once more to take an active part in the work of Government. The organization of French parliamentary life was very well adapted to parliamentary control. Through its big committees, representing all political groupings, the Chamber in peace-time was able to examine in detail all Government bills and all Government action. Those committees ceased to function in Aug. 1914, and did not resume their activities until 1915. When the regular 1915 session of Parliament met on Jan. 12, it was decided, with a view to reducing public sittings to a minimum, to increase the work placed upon those committees. The immediate financial necessities of the country were met by a bill authorizing the issue of Treasury and National Defence bonds. A number of other bills, dealing with points of minor importance, arising out of the war, were also submitted to the House, regulating such questions as naturalization of enemy aliens, marriage by proxy for men serving at the front, and prohibiting throughout the country the sale of absinthe. Throughout the first five months of this year finance occupied the chief place in parliamentary orders of the day, and Ribot, Minister of Finance, experienced no difficulty whatsoever in obtaining all the credits he considered necessary for the prosecution of the war. Outwardly all seemed quiet, but behind the closed doors both of Senate and of Chamber of Deputies Committees, the Government, and particularly Millerand, were being vehemently criticized for their alleged failure to provide the armies in the field with the vast amount of ammunitions of every kind required by trench warfare.

The attack upon Millerand was developed from every side, and the first public contentious debate in Parliament took place on a bill proposed by an advanced Radical, Dalbiez, providing for a vigorous combing-out in war factories and public offices. This bill, although opposed by Millerand, was accepted, though in an amended and somewhat mitigated form, by the Chamber on June 26. On July 1 a less direct attack upon the Minister of War was met, when the Government, forestalling a demand for the appointment of four war under-secretaries, created two such offices, and nominated Joseph Thierry, who was Minister of Public Works in the Barthou Administration, to be Under-Secretary of War for Commissariat, and Justin Godart to be Under-Secretary entrusted with the control of the medical services.

Meanwhile, M. Clemenceau, as president of the Army Committee of the Senate, was preparing a strong case against the whole administration of the War Office, and paving the way to public debate on the organization of parliamentary control, and the general relations which should exist in wartime between the three great organs of war-government, Parliament, Government, and the Supreme Command in the field.

*The Military Control.*—It was inevitable that any political crisis should either affect or be caused by the relations between the Supreme Command and the Government, and in considering the political history of France during the war this fact has always to be borne in mind. Quite apart from the many politicians who, with more vanity than sincerity, believed themselves to be the heaven-sent Carnots of the great war, there was wide-spread and not unfounded discontent with the bureaucratic methods of M. Millerand, and a wonder whether Gen. Joffre, with his "nibbling" methods and his vast patience, were really suited to the supreme control of the army. To these broad causes of dissatisfaction there was added one of a purely political nature, when Gen. Sarrail, who had always been identified with advanced Radicalism, was removed from his command at Verdun. (He subsequently became commander-in-chief at Salonika.) This had aroused the political passions of the Left, and they were still further inflamed by the presence of a practising Roman Catholic at the head of the medical services of the army, and by reports of religious pressure being brought to bear upon French wounded. This feeling came to a head when the Radical and Socialist-Radical groups called upon the prime minister to accept parliamentary control over all war services, and hinted to him that the departure of the Minister of War from the Cabinet would give it increased strength. M. Millerand, who, throughout the crisis, had displayed a fine obstinacy, declined to resign, and Viviani, after a prolonged Cabinet Council, announced that neither he nor any other member of the Cabinet would resign, thus leaving the Chamber the grave responsibility of upsetting the Government by a direct vote. Millerand, at an important sitting on

Aug. 20, vigorously defended his administration, and appealed to the House to support him in seeing that there should be no confusion between the parliamentary control and military authority, the principle he laid down being that "in war, authority and responsibility cannot be divided. Each military chief controls the actions of his subordinates, and is himself responsible for his acts to his superiors. The commander-in-chief is responsible to the Government, which can remove him if it does not approve of his acts." Only Viviani's eloquence, and an uneasy feeling among deputies that the country could not be expected to tolerate in war-time the upsetting of a Government after a debate held behind closed doors, defeated the proposal for the holding of a secret session of Parliament, at which all facts and figures concerning the army should be revealed.

When Parliament reassembled on Sept. 16 all further political agitation was stayed by the imminence of a French offensive in the Champagne, and by the involved state of Balkan affairs. By the end of the first week in Oct. disappointment with the results of allied diplomacy in the Balkans and the indecisive result of the French operations in Champagne led to a renewal of the demand for a secret parliamentary debate. The collapse of the Government was brought about by the resignation of Delcassé, Minister of Foreign Affairs. The division which followed the debate upon that resignation showed clearly that the Viviani Ministry was doomed. On Oct. 29 Viviani, in tendering his resignation to the President of the republic, stated that the last division of the Chamber had shown that a large minority favoured the holding of a secret session, which he had himself formally opposed. He considered it necessary that another should seek to re-create that parliamentary unity which was more than ever necessary to the country.

*New Briand Ministry.*—The new Cabinet was composed as follows:—Briand, prime minister and Foreign Affairs; Viviani, Justice; Gen. Galliéni, War; Rear-Adml. Lacaze, Marine; Malvy, Interior; Ribot, Finance; Méline, Agriculture; Sembat, Public Works; Clémentel, Commerce; Doumergue, Colonies; Painlevé, Public Instruction and Inventions; de Freycinet, Bourgeois, Combes, Guesde, Denys Cochin, Ministers of State; Jules Cambon, ex-ambassador to Berlin, became Secretary-General of the Foreign Office. With its under-secretaries the Government contained 23 members. It was very varied in its political complexion, comprising three Unified Socialists, three Independent Socialists, six Radicals and Socialist-Radicals, two moderate Republicans, one Progressist, and one member of the Right. The inclusion of such political veterans as Méline, Combes, and de Freycinet, who were soon known as the Elder Statesmen, and the placing of a soldier and a sailor at the head of the fighting services, were the only innovations of note, and Briand, in declaring that the motto of his Government was "Peace through Victory," took an early opportunity of assuring the world at large, and the enemies of France in particular, that the change of Government, far from being due to any change of policy, was but a reflection of the country's desire for a more vigorous prosecution of the war. Briand lost no time in pressing forward the first and most important part of his programme—that aiming at coördination of Allied effort in every field of the war, military, naval, financial, economic and diplomatic. With this end in view a number of Allied conferences were held in France during Nov. and a significant change was made in the functions of Gen. Joffre. His command, which had been confined to the armies of the North and the East, was extended so as to comprise the control of all French armies operating in Europe. Thus the Salonika Expedition came within his command. With closer working between the Allies it became necessary to give Joffre freedom for the consideration of large strategical questions, and, with that in view, Gen. Castelnau was appointed chief of the general staff.

Throughout the winter of 1915–6, those efforts for coördination continued in many a wordy conference, but when the Germans began the battle for Verdun, in March 1916, not much progress had been made. The critical situation at Verdun prevented any voicing of the discontent of Parliament at the slow progress made, both with this matter, and with the failure of the Government to make parliamentary control effective in the field. On March 16, Gen. Galliéni was forced by ill-health to resign (he died on May 27). Gen. Roques (b. 1856) succeeded him. He had made a reputation for himself at Verdun.

The remaining months of spring were filled with efforts to obtain Allied coördination, and with the critical development of the Verdun battle. When Parliament met again on May 18, financial requirements once again claimed immediate attention, and, for the first time, new taxation was imposed on the country. The constant political anxiety for parliamentary control, and for frank and full information as to the progress and conduct of the war, was strengthened by events upon the Verdun front, and finally Briand was forced by parliamentary pressure to accept a secret meeting of the Chamber. The immediate cause for this secret meeting was the change in the command of the Verdun armies. Gen. Pétain, who was appointed to the command after a hurried visit of inspection by Gen. Castelnau, was decorated a few days afterwards for having "adjusted a delicate situation." It became known that, before Castelnau's visit, preparations had been made for the evacuation of Verdun and the whole of that region on the right bank of the Meuse. Parliament desired to be acquainted with the elements of the delicate situation which Gen. Pétain had adjusted, and to be assured that, if there were any guilt in the matter, punishment should be awarded. There was also a desire for full information as to the steps taken to organize the Verdun front, for defensive purposes, before the German attack broke on Feb. 21, it having been reported by a member of the House (Major Driant, subsequently killed at Verdun) that the defensive organization was extremely defective. No Government worthy of the name could accept any secret debate which would give to Parliament the opportunity of discussing questions which were the sole concern of the military command, and which would hand over to the passion of politics the stability of command in the field. Briand therefore made it clear to the House that, if there were to be any secret debate, it must not be restricted to points of detail; that the discussion should cover the whole general policy of the Government; and that no vote should be taken in secret sitting.

*The Secret Session.*—For the first time in French history, the Chamber of Deputies constituted itself a secret committee on July 16. As a matter of fact, there was nothing which could be communicated to the House sitting in secret committee, with which its delegates on the Army Committee and Foreign Affairs Committee had not already become acquainted; and, as was remarked by one member, when the Government accepted the idea of a secret meeting, it was only a means of taking the whole country into its confidence. The proceedings, which were stormy, ended on June 22, and, at the public session which immediately followed, a motion of confidence in the Government was carried by 444 votes to 8. The advocates of parliamentary control had made headway, however, for the motion, while declaring that the Chamber desired strictly to refrain from intervention in the conception, direction or execution of military operations, adding that it meant to watch with increased care over the output of munitions and general army supplies. It further indicated the intention of the Chamber to have recourse to the procedure of secret committees, and, with the assistance of the Government, to organize a direct delegation for control on the spot of all services entrusted with army supplies.

The continuance of the battle of Verdun, and the bursting of the struggle of the Somme, made further political action against the Government impossible throughout the summer, although there can be no doubt that, had it not been for the pressure of the front upon internal affairs, Briand's Ministry would not have survived as long as it did. The proverbial luck of the prime minister came to his assistance at a critical moment in the summer, when, on Aug. 28, Rumania entered the war upon the Allied side. It was a brief gleam of good fortune, and probably nothing but the beginnings of a pacific movement on the extreme left of the Socialist wing kept the Government in power in the autumn. Time after time have extremists, by ill-timed attacks, kept the French Ministry from extinction; and when such men as Brizon,

who went to Zimmerwald to discuss peace with German Socialists, daily insulted in the Chamber the ideals for which his countrymen were dying at the front, it was easy for a tactician such as Briand to profit by the indignation aroused.

*Reconstruction of the Ministry.*—These political considerations, and the necessity for the Loan of Deliverance, subscriptions for which were opened on Oct. 5, being undisturbed by political trouble, kept the Chamber more or less quiet until November. The difficulties of the country were, however, steadily growing; and it was apparent that the Government had lost the fund of energy and foresight with which it had started. Economic troubles were becoming extremely irksome; practically nothing had been done, save by dead-letter decree, to stamp out hoarding; transport, both by rail and sea, had been allowed to lapse into chaos, except for military purposes. In the early part of Nov. the Government, conscious of its shortcomings, and anxious to forestall parliamentary criticism, as well as to meet the growing public indignation, appointed M. Claveille, the head of the Western State railway, to be Director-General of Transports and Imports. An under-secretaryship of State for civil and military food supplies was also created, and the post was entrusted to M. Joseph Thierry. A number of food restrictions were also decreed, most of which, except in the remoter districts, remained very much a dead letter. On Nov. 28 all these matters of discontent, to which were naturally to be added the course of eastern affairs, the question of effectives (the 1918 class registration had been voted six days previously), and the High Command, brought about a further secret meeting of the Chamber. At the meetings, which occupied nine days, criticism of the Government was outspoken, and it was only after promising a smaller Ministry and reorganization of the High Command that Briand was able to obtain a vote of confidence. In his reconstructed Ministry Briand remained prime minister and Minister of Foreign Affairs; Ribot at Finance; Adml. Lacaze at Marine; Malvy at the Interior; Viviani stayed in the Ministry with the consolidated portfolios of Justice, Public Instruction and Labour; Clémentel took over the new portfolio of National Economy (Commerce, Industry and Agriculture); Herriot became Minister of Transport and Supplies; Albert Thomas, Minister of Armaments; Doumergue, Colonies; Loucheur, Under-Secretary for Armaments; and Gen. Lyautey was transferred from Morocco to the Ministry of War.

*A Ribot Ministry.*—This new combination had a brief and exciting existence. Accusations of dictatorship were made as soon as Briand, thinking to meet the Chamber's demand for firmer government, asked for power to settle a number of questions by decree. Both the deputies and the senators held a number of secret sessions, in which nearly every one of the Government's acts was vehemently criticized by speakers on all sides; and, early in 1917, it was clear that the Ministry could not long continue to face the growing hostility of Parliament. It died of anaemia. Its leader, wearied by the strain of office, and harassed almost beyond bearing by incessant criticism, partly no doubt patriotic, and also without doubt very largely political, could no longer see his way clear through this very dark period in the war. He lacked the reserve strength of character and the men required to deal with economic difficulties and to stir the country out of the war-weariness which was creeping over it. The immediate cause of his collapse was the resignation of Gen. Lyautey, a straightforward soldier with a horror of politics, and the supple compromises of the politicians. He resigned on March 14, after voicing his distrust of secret sittings. Briand failed to find a successor to him, and the whole Cabinet went on March 17.

M. Ribot met the Chamber four days later with a Ministry in which there were not many changes. It was composed as follows: Ribot, prime minister and Foreign Affairs; Viviani, Justice; Painlevé, War; Adml. Lacaze, Marine; Thomas, Munitions; Thierry, Finance; Malvy, Interior; Steeg, Public Instruction; Desplas, Public Works; Clémentel, Commerce; Fernand David, Agriculture; Violette, Supply; Léon Bourgeois, Labour. This new combination was slightly more Radical than its predecessor, and its chief point of interest was the nomination of Painlevé to the Ministry of War. When the Briand Ministry was reconstructed in Dec., Painlevé declined that portfolio, and joined the Left in criticism of Briand's war-leading.

*The Army Command.*—One reason for this refusal had been the appointment of Gen. Nivelle to the High Command, and it was inevitable that one of the first things to be undertaken by the Government was a reorganization of the army command. Gen. Nivelle had prepared plans for a general offensive to be started on the Champagne front at Easter-time. He was allowed, after much criticism from the Ministry of War and from other commanders, to proceed with his arrangement in a modified form. Although the offensive produced some fruit, in the shape of prisoners and guns captured and territory re-won, it failed entirely in its main objective. Gen. Nivelle complained bitterly that the responsibility for this failure lay on the shoulders of M. Painlevé, whom he charged with having intrigued against him with generals under his command, and with having, by exaggerating losses sustained by the French in the operations, undermined the confidence of the troops in his leadership. He also charged the Government with not having done its duty in repressing the pacifist and seditious propaganda in the rear, which had affected the *moral* of some of his troops.

Gen. Pétain was appointed to the chief command on May 15, Gen. Foch becoming chief of the general staff with very extensive powers. May and June were filled with labour troubles of a very wide-spread nature. They coincided with mutinous developments among the troops at the front, and with the demand of the Socialists for passports for Stockholm to take part in the proposed international meeting for the discussion of peace. It was evident that behind all this agitation there were foreign men and foreign money. Labour troubles were smoothed down, a number of concessions being granted in the way of shorter hours; the military troubles led to the execution of a good many of the ringleaders, and also to attempts being made to improve the system of leave, and to release the older men from service at the front. Public opinion, which had been rendered very uneasy by these many signs of weakening *moral*, both military and civilian, became even more alarmed as the result of M. Caillaux's activities in preparing the way for peace. An attack delivered in the Senate by M. Clemenceau upon the way in which Malvy, the Minister of the Interior, had allowed a whole number of anti-patriotic organs to carry on pacifist and pro-German campaigns in France brought matters to a head.

*Painlevé Premier.*—By the end of Aug. the position of the Government had become impossible. M. Malvy resigned on Aug. 31, and a week later the whole Cabinet followed suit. The Socialists refused to support Ribot in forming another Cabinet. He had incurred their enmity by refusing to allow their delegates to attend the Stockholm meeting, and they made the continued presence of any of their number in the Government dependent upon utterly inacceptable conditions of control, which, had they been put into effect, would have made the Government the prisoner of a Socialist Soviet system. Painlevé, however, found more favour in their eyes; but he refused to exclude Ribot from the Ministry, and, in spite of Socialist and Socialist-Radical opposition, the latter stirred up by M. Caillaux, retained him as Minister of Foreign Affairs. The new Ministry was Radical and Socialist-Radical in a more pronounced degree than any previous war Cabinet. Its birth was attended by intrigue and bitter party feeling. It represented the last and despairing effort of the old Radical gang and the Socialist extremists to save themselves from the advent to power of Clemenceau, whose fearless exposure of M. Malvy's backslidings had earned him tremendous popularity in the country. Painlevé was too closely identified politically with Malvy and his friends for it to have been possible for him to control the gathering storm. When he became prime minister, the first of the long series of treason scandals had been opened up. Almeyreda had died in prison; Bolo was in gaol; and more than one member of the Chamber of Deputies was involved in suspected dealings with enemy subjects.

*Clemenceau in Power.*—When, on Oct. 5, a definite accusation of treason was made against M. Malvy, the days of the Painlevé

Government were numbered. M. Caillaux, it was clear, could not escape searching investigation into his war-time activities. On Nov. 13 the Ministry was defeated by 279 votes to 186, and all the eleventh-hour efforts of Socialists and Socialist-Radicals could not keep Clemenceau from power.

Clemenceau quickly got to work, and showed, by the choice of his colleagues, that he intended to have as little as possible to do with the political patchwork system whereby each successive prime minister regrouped around him all the eminent failures of his predecessor's Cabinet. He himself, as a fighting leader, took the only portfolio which in his eyes had any importance at the moment—that of the Ministry of War. The rest of his Cabinet was as follows:—Nail, Justice; Pichon, Foreign Affairs; Pams, Interior; Klotz, Finance; Georges Leygues, Marine; Clémentel, Commerce; Claveille, Public Works; Loucheur, Munitions; Lafferre, Public Instruction; Henri Simond, Colonies; Colliard, Labour; Jonnart, Blockade; Boret, Supplies and Agriculture. Of these only Klotz, Clémentel, Claveille and Loucheur had held office previously during the war. M. Clemenceau surrounded himself by five under-secretaries at the War Office, one of whom was charged with the administration of military justice. The ministerial declaration read to Parliament on Nov. 20 was in its tonic effect upon the country as stimulating as a victory at the front. "The war and nothing but the war" was, he declared, his Government's one thought. "We have one sole, simple duty," he said, "to stand fast with the soldier; to live, suffer and fight with him; to cast from us everything that is not for our country." The rhetorical portions of his declaration amounted to a moral mobilization of the whole country. The concrete passages were concerned with treason, food restrictions and finance. Towards treasonable propaganda the Government would act without mercy. All such cases would be tried by court-martial; they would tolerate no more pacifist campaigns, neither treason nor half-treason. Within the month effect had been given to this determination. Those cases which had already been opened were handed over to the military legal authorities; the Malvy case had been sent before the High Court; the prefect of the Paris police had been removed from his post; the Government had applied for the suspension of parliamentary immunity in the case of Senator Humbert, Joseph Caillaux and two other members of Parliament. The parliamentary immunity was suspended before the end of the year; Caillaux was arrested on Jan. 14.

*The Treason Scandals.*—The chief *affaires de traison* which were investigated by military justice and the High Court were those arising out of M. Caillaux's visits abroad and activities at home, from M. Malvy's administration as Minister of the Interior, the sale of *Le Journal*, the policy of the *Bonnet Rouge*, and Bolo's connexion with both these last-named matters. All the cases were closely connected one with the other, and the prosecution sought, in the conduct of each one of them, to show that M. Caillaux was involved in all. Bolo was on friendly terms with Caillaux and Malvy, and had acquired an interest in the *Journal* and the *Bonnet Rouge*. His was the first case to come for trial before the third Paris court-martial. The case opened on Feb. 4 1918, when Bolo and a subordinate figure, Porchère, were in the dock, Cavallini, an Italian, who was also charged, being in Italy. Lt. Mornet, acting as public prosecutor, outlined the case. He charged Bolo, under nine different clauses of the penal, military and criminal code, with "having entered into communication with the military power of Germany, notably through the ex-Khedive of Egypt, with the object of favouring enemy undertakings; having with the same object in view received from Cavallini moneys sent by the German Government to the ex-Khedive in order to create a pacifist movement; having in 1915 endeavoured for the purposes of the enemy to buy shares in the *Figaro* with money of German origin; having in 1916 received money from the German Government for the purpose of creating a movement of opinion favourable to the enemy in the French Press; having furnished to M. Humbert, director of the *Journal*, enemy money with a similar intention." The prosecution showed that Bolo had made efforts, ever since 1915, to corrupt the French Press. After Germany had lost the first battle of the Marne she turned round in search of other weapons with which to restore her military fortunes. Bolo, who was a hanger-on of the former Khedive of Egypt, went to see him in Switzerland, where he was playing an important part in the German system of espionage and intelligence. Bolo suggested pacifist operations in the French Press. Herr von Jagow, then German Minister for Foreign Affairs, accepted the scheme submitted and promised to support it with 10 monthly payments of 1,000,000 francs. In March 1915, the ex-Khedive received 2,000,000 marks from Germany, and paid a portion of this sum to Bolo, who invested 150,000 francs in the *Rappel*, and tried to obtain interest in *La Revue*, the *Cri de Paris*, the *Figaro*, and *l'Information*. The German Government, apparently considering that it had not received its money's worth from this payment, a large portion of which was devoted by Bolo to the settlement of his personal and pressing debts, did not carry out the rest of the programme. Bolo thereupon played for higher game, and, having obtained an option on the controlling interest in the *Journal*, went to America, where he was provided with £336,700 by the German Government, £220,000 of which he used to purchase shares in the *Journal*.

The Bolo case aroused an immense sensation, not only because of the revelation of the danger to which France had been exposed from treason from within, but also on account of the high position occupied by many of the witnesses, and perhaps especially by reason of its bearing upon the cases of MM. Caillaux and Malvy, with both of whom, as the correspondence produced showed, Bolo had been on intimate terms. Fruitless attempts were made by the defence to compromise the President of the republic, Poincaré, and to discredit the Clemenceau Government. Eleven questions were put to the court on the last day of the trial, Feb. 14, and to each the unanimous reply of guilty was returned. Bolo was condemned to death, Cavallini was sentenced to death *in contumaciam*, and Porchère was sentenced to three years' imprisonment. Bolo, after appealing both to the courts and to the President of the republic against his sentence, after trying to save his life by eleventh-hour revelations, was executed at Vincennes on April 17.

*Bonnet Rouge Trial.*—Twelve days later the gang of the *Bonnet Rouge* came before the third court-martial. In this case there were seven accused, four of whom were charged with intelligence and commerce with the enemy—Duval, Marion, Goldsky and Landau; one, Joucla, with intelligence with the enemy only; and two others, Vercasson and Leymarie, principal private secretary of the Minister of the Interior, with complicity in commerce with the enemy. The first notification of the case was the arrest at the Franco-Swiss frontier of Duval, who was then found to be the bearer of a German cheque for over six thousand pounds. The investigations of the French police showed that the *Bonnet Rouge* was the centre of a chain of newspapers established in Paris, with no other apparent purpose than that of spreading despondency and doubt among the French as to the justice of their cause, and suspicion as to the honesty and loyalty of their Allies. The arrest of Almeyreda soon followed that of Duval. Almeyreda was an unsavoury and needy hanger-on of politics, who had fished in the troubled waters of anarchist and communist ideas before the war; had furnished Caillaux with a bodyguard of toughs to protect him during the trial of his wife for the murder of Calmette, and remained in touch with him as well as with Malvy throughout the war. He founded the *Bonnet Rouge* in 1913 as a weekly paper, and with funds supplied by Caillaux, after the murder of Calmette, transformed it into a daily publication in 1914. It was on his representations that, when the war broke out, M. Malvy, then Minister of the Interior, agreed not to proceed with the arrest of those who were nationally suspect, and of whom a list had been prepared in anticipation of war. This list included a number of political undesirables, among whom was Almeyreda himself. He was found dead in gaol on Aug. 14 1917, and, although he was known to be a morphine maniac, the circumstances of his death, and the interest which certain highly placed personages had in his disappearance, led to definite charges against the prison authorities. At the trial it was shown that Duval had received about £40,000 from a Mannheim

banker called Marx, who acted as distributor of German Secret Service money in Switzerland during the war. It was also shown that in the Ministry of the Interior complete chaos prevailed in the police services, which were themselves in conflict with the secret services of the War Office; that it was with the connivance of M. Malvy (who, as Minister of the Interior, had subsidized the *Bonnet Rouge*) and his *chef de cabinet*, Leymarie, that Duval obtained passports for some of his visits to Switzerland.

The trial ended on May 15, when Duval was sentenced to death, Marion to ten, Landau to eight, Goldsky to eight and Joucla to five years' imprisonment with hard labour. Leymarie was sentenced to two years' imprisonment and a fine; and Vercasson to two years' imprisonment with benefit of the First Offenders' Act, and a fine of 5,000 francs. Duval's appeal was dismissed on July 11, and he was shot a few days afterwards, on the eve of the opening day in the proceedings against M. Malvy, who, for three years during the war, and in five successive Governments, had been Minister of the Interior.

*The Malvy Case.*—Malvy appeared before the Senate, sitting as a High Court, on July 16 1918. The charges against him, in practice though not in law, were first formulated by Clemenceau in his attack upon the Ribot Government in July 1917, when he showed how greatly negligent administration at the Ministry of the Interior had encouraged defection, both at the front, and behind the lines. That attack led to Malvy's resignation, and to the fall of the Ribot Government, and later, in Oct. 1917, it was given a sensational sequel by the Royalist, Léon Daudet, editor of the *Action Française*, who, acting as chief spy-hunter during the war, had aroused public and Parliament to a knowledge of the danger of allowing enemy agents and traitors complete freedom of action in France. In his newspaper for months he had attacked Malvy; and on Oct. 4, in a letter addressed to President Poincaré, he roundly accused Malvy of having betrayed France during the three years' term of his office during the war; of having communicated the French plan of attack on the Chemin des Dames in the spring of 1917 to the enemy, and of being partly responsible for the military mutinies which followed that attack. So slow is the machinery for bringing a member of Parliament to trial before the High Court, that the report of the Senate Committee on the charges was not read until July 16. It was upon that report that M. Malvy was charged with a number of acts committed between 1914 and 1917, calculated to favour the cause of the enemy, and to incite French soldiers to revolt. The reporter, Senator Pérès, briefly dismissed the definite charge of treason made by Daudet, but examined in some detail the effect of Malvy's policy of tolerance and slackness on the *moral* of troops at the front. He showed that while first Gen. Nivelle, and afterwards Gen. Pétain, were vehement in their requests for sterner measures in dealing with defeatist propaganda, Malvy and his police turned a deaf ear towards them, and that Malvy actually, on the eve of the military mutinies which affected over a hundred French battalions in the front zone, complained of "myths that are too easily believed." The military and civil police were constantly at warfare. The soldier urged that foreign and other suspects should not be permitted to roam about the country; and while Malvy maintained with equal vigour that it would disturb public opinion to make many arrests, the police in his care actually furnished passports and gave missions to men whom their own services had denounced as enemy agents. One passage of the report which had special bearing on the approaching Caillaux case was that in which it was shown that when Caillaux was visited by an Austrian peace agent, and while he was being shadowed by the police, he was warned by Malvy.

The Public Prosecutor, in his opening, ignored Daudet's accusations, and charged Malvy with culpable negligence in the administration of his office; with having been, instead of a servant of his country, the servant of a politician, Caillaux, who desired to keep his power in politics although he was himself discredited and out of office. Instead of acting as the sword against the suspect and the treason-monger, whenever the name of Caillaux was involved he acted as the shield, ordering that surveillance and prosecution should be stopped, restraining what zeal his police possessed in controlling and stopping the activities of secret anarchist printing works, revolutionary committees, and the spreading of Bolshevik and pro-German doctrines. The Public Prosecutor showed that Malvy had been duly warned in a document drawn up by one of his own chief officials, known as the Red Book. This work, of which six copies only were made, was given to the President of the republic, the prime minister, the prefect of police, Hudelo, and Malvy himself. The vital period in the case was that which followed Gen. Nivelle's unsuccessful offensive in the Champagne. It was then, as Caillaux subsequently wrote, in *Mes Prisons*, that his own policy of conciliation with Germany, and Clemenceau's policy of victory over Germany came to grips. The country was low-spirited, war-weary, and suffering from a bad political and economic leadership. It was at this time that the defeatist propaganda became most intense. The agitation for a Socialist Peace Conference at Stockholm had made considerable headway among the people; the *Bonnet Rouge* and all its offspring were most active; men coming back from leave were addressed by agitators, given seditious literature; the *Bonnet Rouge* was distributed free in the trenches; troop-trains returning from the front had on several occasions to be kept out of Paris, so clamorous were the men for peace; in 118 battalions, including some of the best troops in the French army, mutinies broke out and had to be repressed with military severity; the streets of the capital were filled with strikers, and labour troubles were spreading through the provinces. All that the military leaders had dreaded had come to pass, and any action Malvy took was always in favour of the agitator.

The evidence given at the trial by police officials, civil servants, and soldiers, concerned with the *moral* of the army and employed in the intelligence services of the country, showed that the whole machinery of police and counter-espionage had been devoted to the protection of political patrons, their friends and allies, rather than to defending France and confounding the designs of the enemy. Complete anarchy prevailed. Police records were lost, suppressed or stolen by the various personages most concerned. Official fought official, department was arrayed against department, ministry against ministry, to such an extent that the public and the Senate could have been pardoned in believing that Malvy and his friends and officials thought themselves engaged, not in a struggle for national existence, but in a civil service war. Political capital was naturally made by the defence out of the fact that Cabinet sanction, delivered by successive prime ministers, Viviani, Briand and Ribot, had been obtained for the acts performed and the policies pursued by Malvy as Minister of the Interior in their respective Governments; and the solidarity of politicians was shown when those three former prime ministers, with the latitude allowed by the elastic customs of the law, made with their testimony three speeches for the defence.

The trial came to an end on Aug. 6, after a lot of legal and political quibbling, when the Senate, definitely dismissing Daudet's charge of direct treason, found Malvy guilty of "forfaiture"—a charge correspondent to the old one of "forfaulture"—by 101 to 81. This amounted to declaring that Malvy had been guilty of such gross general negligence as amounted to treason. The Court found:—

"That M. Malvy, acting as Minister of the Interior, and in the exercise of his functions from 1914 to 1917, has failed in, violated and betrayed the duty of his task in conditions which place him in a position of forfeiture, and has therefore come under the criminal provision of Art. XII. of the law of 1875. The Court therefore condemns M. Malvy to five years' exile, but without civic degradation."

The verdict pleased no one in particular, but it was delivered on a day when Gen. Foch's nomination to be Marshal of France marked the beginning of victory. It aroused no political or public sensation, and, on Aug. 19 Malvy, after protesting his innocence, left Paris for San Sebastian and exile.

*The Caillaux Trial.*—Caillaux did not actually come up for trial until Feb. 17 1920, although it was the third time that the Senate had sat as High Court to consider his case. The previous dates in the case were:—(*a*) demand for suspension of Caillaux's parliamentary immunity, Dec. 11 1917; (*b*) immunity voted by

Chamber, Dec. 23; (*c*) Caillaux arrested, Jan. 14 1918; (*d*) decision to try him before High Court of Senate, Oct. 1918; (*e*) Senate Committee's report on case, Sept. 17 1919. All the time that Caillaux was under arrest, a part of which period he spent in a nursing home, he was under constant examination, either by the military authorities, or by Senator Pérès, who was appointed to report on his case. The indictment against Caillaux was one of having "since the declaration of war, in 1914-5-6-7, in France and especially in Paris, and abroad, sought to undermine the security of the State abroad by manœuvres, machinations, and intelligence with the enemy, favouring the undertakings of the enemy against France or against her allies fighting against a common enemy, and of such a character as to favour the progress of enemy arms; crimes punishable by Arts. 77 and 79 of the Penal Code, and by Arts. 205 and 64 of the Code of Military Justice." The act of accusation reproached Caillaux with the fact that while the rest of his colleagues in Parliament were pursuing a common national policy, Caillaux remained outside that community and was indeed the man upon whom Germany pinned her hopes of a premature peace. This document maintained that when Germany gave 20,000,000 francs for the purchase of the *Journal* to Lenoir, whose father had been employed by Caillaux during his secret Moroccan negotiations, she saw behind Lenoir Caillaux himself, and that the same thought inspired them in their dealings with Bolo. This tendency of the German Government to look upon Caillaux as their man was further shown by German censorship and army orders forbidding any praise of Caillaux which might compromise a person "whose activities may still be useful to us." This German trust in Caillaux was, according to the prosecution, based upon his pre-war negotiations with Germany in connexion with Morocco, and was further explained by Caillaux's connexion with the *Bonnet Rouge* and its group of defeatist newspapers. Caillaux, the act of accusation roundly declared, was "the pivot of treason." His own actions in S. America in 1914, and in Italy in 1916, went to support the arguments of the prosecution. In S. America, whither he was sent on a mission created in order to keep him out of mischief in France, he fell straight into the hands of a German agent, who kept his Government informed of Caillaux's actions and conversations. On his return from S. America at the beginning of 1915 he received the visit of Hungarian agents acting the part of Germany, who desired to engage in peace negotiations with him. During his Italian journeys Caillaux was again the centre of all the disaffected elements, and his conversation was such as to arouse alarm in the minds of the Italian Government and the foreign embassies and legations. He spoke freely of France being exhausted by the war, and of the time when he would assume power again and conclude peace with Germany.

In a safe which Caillaux had rented in a Florence bank, a number of extremely important documents were discovered, among them being a plan for a *coup d'état*. This plan provided for a complete change of all army commanders and generals; for the dismissal of the Chamber; for the summoning to Paris of certain regiments; for the arrest of a number of the chief patriotic politicians and newspaper directors; and the creation of a small ministry composed of dependable men. Peace, according to these notes, was only to be made after a referendum, and a law, which Caillaux himself called the Rubicon, was to be passed according to which for a period of 10 months the President of the republic could govern by decree. The document included a list of possible collaborators, and mentioned among those people who might be used, Landau, who was serving a sentence for treason, and Almeyreda, who committed suicide in prison while awaiting his trial on the same charge. Ceccaldi, a Corsican friend of Caillaux, was to be appointed prefect of police, in control of all the Secret Service of France. All the people belonging to the Royalist *Action Française* were to be arrested and tried for treason.

Caillaux defended himself with the utmost vigour. He declared that it was not his fault, or by his desire, that all the undesirable agents of Germany looked upon him as their prey; that he was a patriot who had a policy. That policy might be right or wrong, but the mere fact of having opinions could not be regarded as a crime. As to the plan for the *coup d'état*, it consisted simply of notes jotted down with the natural detachment of a politician, and there was nothing to show that they represented his real convictions. He vigorously fought witnesses from Italy and S. America, but in spite of all his mental ability, was unable to furnish the High Court with a plausible excuse or explanation of the fact that he had been, throughout the war, the magnet for every intriguer for premature peace. On April 23 1920, Caillaux was condemned to three years' imprisonment, for ten years to the loss of his civic rights, and for five years to reside within a zone to be indicated to him by the Government, as well as to the costs of the case, amounting to about 53,000 francs. This verdict meant, since he had been already imprisoned for three years, that he was released the next morning. He went to live at Mamers, and was forbidden to come to the capital without permission from the Government. The formal verdict of the Court found him guilty of having been in relation with enemy agents in S. America, in Paris, and in Italy; with having been in correspondence with the enemy; and with having, owing to "guilty thoughts or ambitions," given to the enemy information of the greatest value to him for the conduct of his defeatist propaganda in France; but exonerated him from the guilty intention required by Art. 77 of the Penal Code. The verdict was given at a time when the whole trial had ceased to have the burning importance it would have had during the war, and when Caillaux, in any case, would have had to disappear from French political life.

*The Journal.*—In addition to Bolo, Senator Charles Humbert, who had played an important part in the Army Committee of the Senate; Pierre Lenoir, the son of a wealthy publicity agent, who had been employed by Caillaux; Desouches, an ex-barrister; and Georges Ladoux, captain of infantry, employed at the Central Intelligence Department in Paris, were involved in the charges arising from the purchase of the *Journal*. They were brought to trial before the Third Court-Martial, on March 31 1919. After sitting for 34 days, the Court found Lenoir guilty of intelligence with the enemy; Desouches guilty of commerce with the enemy; and acquitted Charles Humbert and Capt. Ladoux. Pierre Lenoir was condemned to death on May 8 and Desouches was sentenced to five years' imprisonment, and a fine of 20,000 francs. These were the main treason cases, but a host of minor treasonable fry was brought to trial by the energy of Clemenceau's military justice.

*Clemenceau and Man-power.*—He was no less vigorous in keeping the promises of his ministerial declaration in other directions, and the country was given an example of what resolute government can achieve when it has a clear aim before it, and takes its courage in both hands. The Painlevé Government, in a desperate effort to cling on in office, had declared it impossible not to release the older men from service in the army. Clemenceau tackled the man-power nettle in quite another manner. He roundly informed the Chamber that, in spite of approaching American aid, thanks to the disaffection of Russia and the general losses suffered by the French armies, the outlook for the future was not bright. The army demanded more men, and Clemenceau, who declared that his only war aim was to conquer, lost no time in getting them. The debate on Dec. 28 1918 showed that the Chamber intended to support Clemenceau who, far from holding out hopes of release to the older men with the colours, reminded the House that there were 1,200,000 mobilized men working in the rear who would if it were at all necessary have to return to the colours. He announced that the 1919 class would at once be got ready for active service, and that two classes of released conscripts would at once be called back to the army for a period of six weeks or two months, in order to carry through the programme of defensive works declared by G.H.Q. to be indispensable. A rigorous comb-out of all Government offices was carried through by M. Jeanenney, and all mobilised men of the 1914 class employed in State establishments in the rear were placed at the disposal of the commander-in-chief. Heavy increases in taxation, and a rain of decrees restricting consumption, closing shops and suspending manufacture of certain goods, were further evidences of the Draconian nature of the Government's

policy. The food restrictions, however, remained (especially in the large towns) very largely a dead letter. From this point of view Great Britain was far ahead of France. Nevertheless, life was made irksome in more than one direction, and with events going far from well at the front; with great raiding activity on the part of the German air squadron; and with the opening of the bombardment of Paris on March 23 by a gun situated over 70 m. distant from the capital, the French people, and the Parisian population in particular, had many reasons for despondency.

The alert courage and tireless energy of Clemenceau throughout those dark months acted as a tonic both on the army at the front, where he was known as *Père la Victoire*, and upon the civilian populations in the rear. Clemenceau was constant in his visits to the trenches, whence he always returned with a fresh store of serene confidence. The appointment of Gen. Foch to be chief of the western front was also bracing in its effects. Throughout the summer the Government was called upon to deal with some firmness with the growing section of extremists in the Socialist and Syndicalist parties, which, with every fresh reverse in the field, redoubled their opposition to Clemenceau. By the first week of June the question of the defence of Paris had again been considered, and some preliminary work had been done in preparing plans for evacuation. By June 25 the department of the Seine was declared to be within the army zone. Confidence in the army was however markedly greater than it had been when Paris was imperilled in 1914. It received a striking justification when the great French counter-offensive broke mid-July.

*The Armistice.*—From that day to the signature of Armistice on Nov. 11 1918 the political history of France was written by the triumphant armies sweeping the Germans out of the country. The population had been prepared for victory, and in Paris had seen for some weeks tangible signs of the discomfiture of the Germans, in the masses of captured cannon which filled the Place de la Concorde and lined the Champs Élysées up to the Arc de Triomphe. When it was announced, on the morning of Nov. 11, that the Armistice had been signed, the whole country gave itself up to rejoicing, while Allied leaders continued the preliminary discussions with regard to the meeting of the Peace Conference. The month of Nov. was filled with scenes of triumph in the liberated regions and in the recovered provinces of France, where the inhabitants gave to the returning French troops a welcome which had not grown any the less cordial for keeping. The King of the Belgians and King George both paid official visits to Paris. King George, accompanied by the Prince of Wales and Prince Albert, arrived in Paris on Nov. 28 for a visit of two days. Great cordiality was the tone of the official speeches, and of the public reception given to the British sovereign.

*Peace Conference.*—Opposition to Clemenceau, which he had with ruthless methods kept under in defeat, dared not show itself while the German armies were being swept beyond the frontier. When the Armistice was signed, however, it again became apparent in Radical-Socialist and Socialist quarters, and even among Radicals of a less extreme character, who felt that, while Clemenceau might be an excellent man for the waging of war, he was not likely to prove a satisfactory negotiator of a peace by which the whole future of the world would be settled. Such was the overwhelming popularity of Clemenceau, however, that this reaction against his almost dictatorial power made but a faint ripple on the political surface. With his customary sturdy self-confidence, Clemenceau never for an instant contemplated leaving the making of peace to other hands than those which had forged the victory. He refused to accept a general debate upon foreign policy, and turned a deaf ear to all parliamentary criticism of his qualities as a peacemaker. The opposition brought matters to a division on Dec. 17, but could only muster 170 votes. A frontal attack upon the Ministry was again begun on Dec. 26, when some of the motives animating the opposition were clearly expressed. A great number of parliamentarians felt indeed that it would be unwise to permit a one-man Government such as that of Clemenceau to negotiate peace. By private intrigue, and in the public press, Clemenceau was urged to go back to the cabinet system which prevailed throughout the war until his arrival in power, and, if not to form a coalition Ministry, at least to include among the French delegates to the Peace Conference some of the political leaders of the country, such as Briand, who were not in his Ministry. The debate ended on Dec. 29, when Clemenceau and Pichon outlined the attitude the French Government would adopt towards questions of peace. During its course the Government was invited by the Socialists Marcel Cachin and Albert Thomas, and by the Radical-Socialist Franklin-Bouillon, to declare its policy with regard to nearly every world problem, including the League of Nations, the frontiers of Alsace-Lorraine, the future of the Saar, the resumption of relations with the Vatican, the left bank of the Rhine, the Middle and Near Eastern questions, Africa, and Russia. Clemenceau frankly stated that although the old political system of the world appeared to be discredited, he still remained faithful to it. He pointed out that, had that old system been developed, had the United States, Great Britain, France and Italy, before the war declared that whoever attacked one of them would have to expect the other three to join in the task of common defence, there would have been no war. It would be his aim, he said, to preserve during the Peace Conference the alliance of those four Great Powers, and he would make every sacrifice to maintain that entente. He declined to be drawn into any further and more detailed explanation of the policy he would pursue at the Conference, pointing out that, although he desired to obtain satisfaction for every just claim of France, there might be some which would have to be sacrificed in the interests of humanity in general, and that he did not want to arouse hopes which might be doomed to disappointment. He declined on political grounds to discuss the arguments which he intended to use in negotiation with the other Allied statesmen. The division figures gave the Ministry a vote of confidence by 398 to 93, a demonstration of parliamentary support almost as striking as that of the public support given to Mr. Lloyd George by the general elections on the eve of peace.

The French opposition, during this skirmish, made much of President Wilson's presence in Europe. He arrived in Paris on Dec. 14. In France his various messages, his notes to Germany and to the Allies, had been read by large masses of the people as heralding the dawn of a new era. They appealed by their very ambiguity of phraseology to the latent idealism of the Latin mind. This somewhat ignorant and crude emotion was fostered by the authorities through the press, which for weeks before his departure from America was busy fanning enthusiasm for the great American who was to put into effect the teachings of the Sermon on the Mount. Other sections of the community were led by motives of quite another nature to acclaim President Wilson as the great leader of civilization. While the official press was loud in praises, for reasons of courtesy no doubt, but mainly for reasons of policy, the extremists endeavoured to make the most of Wilson, to wrest him, as it were, from the arms of Clemenceau and his supporters. They did their utmost to exploit the difference of character and of outlook which without doubt existed between Clemenceau and the President. Both these forces, together with the undoubted enthusiasm aroused by America's participation in the war, led to Wilson being given a reception in France such as had never before welcomed a foreign chief of state. Clemenceau's attitude towards the League of Nations, to take but one point of difference between the two men, was that he was quite prepared to study the idea, and even to give it a trial, but that until that safeguard of international peace had proved its efficiency he could sacrifice nothing which helped in any way to build up the security of France against aggression.

The opposition to Clemenceau also sought to make capital for internal political purposes out of differences of opinion between the British and French Governments as to the policy to be pursued towards Russia. Under the influence of Marcel Cachin and Moutet, two Socialist deputies who had visited Russia after the revolution, the Socialist party was steadily tending towards support of Bolshevist principles, and bitterly resented Clemenceau's refusal to accept Russian revolutionaries as his political gods. In spite of the overwhelming size of the Government majority at the end of the debate on Dec. 29 1918, his opponents,

although defeated, were not dismayed, and piled up a mass of interpolations upon every imaginable question of home and foreign politics. On Jan. 16 1919 there were no fewer than 13 interpellations before the Chamber waiting for a day to be fixed for their discussion. Clemenceau said that he could not possibly agree to resume the debate which had already ended in a vote of confidence for the Government. He pointed out that the Peace Conference had already begun its labours, and that if the Government were to be allowed to work properly therein, the Chamber must exercise its right of interpellation in a moderate spirit, and refrain in public debate from making capital out of supposed divergencies of opinion between different Governments. As in the matter of choice of the French peace delegation, so in this matter, Clemenceau relied upon his popularity with the country to get for him his own way. Instead of nominating, as he had been urged to do, eminent politicians to the peace delegation, he chose his collaborators at the Conference from his own Ministry and his own officials. M. de Tasta, French ambassador at Berne, was appointed general secretary of the Conference; the other delegates being Pichon, Minister of Foreign Affairs; Klotz, Minister of Finance; Jules Cambon, former French ambassador in Berlin, and André Tardieu (b. 1876), High Commissioner for Franco-American Affairs. Of these men the last was, after Clemenceau, the most important member of the delegation, and he was destined in later days to become the chief defender of Clemenceau and the Treaty of Versailles in the long campaign made against both in Parliament. He was an attaché at Berlin in 1897, acted as prime minister's secretary under Waldeck-Rousseau until 1902; he then became foreign editor of the *Temps*, where he made his influence widely felt; he has held chairs at the École des Sciences Politiques and at the École de Guerre; he entered French politics in 1914; acted as censor at the beginning of the war; served in the field until he was invalided out, when he was appointed French High Commissioner to the United States.

*Clemenceau and the Opposition.*—In France more than in any other country the actions and deliberations of the first six months of 1919 were to form the bulk of the political raw material of the country for years to come. The presence of the Peace Conference in Paris, moreover, had a very great influence upon the whole affairs of the country. Delegates swarmed in the streets of the capital. There were no fewer than 70 of them at the first sitting. Each of them was accompanied by a cloud of experts, secretaries and other minor officials. They filled the hotels and restaurants, and contributed very largely to increasing the almost prohibitive cost of living. The British delegation occupied two giant establishments, the Hotels Astoria and Majestic; the Baltimore and La Pérouse hotels accommodated minor officials; and special printing works were built for the British delegation in the Bois de Boulogne. Mr. Lloyd George and Mr. Balfour occupied large flats in the rue Nitot opposite the Bischoffsheim residence which President Wilson, after leaving Prince Murat's palace, made his home. The American delegation was housed at the Hotel Crillon, and there was hardly a single state represented which did not have one hotel of its own. The press had the over-magnificent residence of the late M. Dufayel in the Champs Élysées placed at its disposal as a club. In spite of this gathering of diplomats, the hangers-on of diplomacy, and statesmen, there was but very little of the public "junketing" which marked the Congress of Vienna. Clemenceau would have none of it, and this feeling was shared by Lloyd George and President Wilson. Any socially brilliant functions which might have been held, would have aroused comment in Parliament, and both Clemenceau and Lloyd George were acutely conscious throughout the proceedings of the importance of looking after their respective Chambers.

Clemenceau, although strong in repeated and heavy votes of confidence, was nevertheless aware that the trust reposed in him by the Chamber of Deputies was due rather to the fact that the Chamber of Deputies had no alternative than that it loved him for himself alone. On several occasions during the Conference, when a point which he considered vital for France was at stake, he threatened to resign rather than to ask his Parliament to accept the suggested compromise. He was attacked with the utmost ferocity in the years which followed the signature of peace, for having sacrificed the interests of France to the friendship, both personal and political, which he had always entertained for Great Britain. During the progress of the Conference, however, his critics either did not dare or did not care to come into the open. Clemenceau's appearances in the Chamber were few and far between. He reserved his strength, his patience and his passion for the discussion of peace, and left the Chamber to glean what information it could through the public press and the workings of its various committees.

He was forced to suspend his work for a time on Feb. 19. As he left his house in the rue Franklin to drive to the Ministry in the morning a French anarchist, Émile Cottin, emptied a Browning pistol into his car. He was wounded by one of the bullets below the left shoulder-blade, and stood the shock with extraordinary calmness, transacting business in his own house within a few hours of the attempt. As week after week passed without showing any perceptible advance towards the conclusion of peace, and without there being any sign of the Government intending to consult Parliament with regard to the terms, considerable dissatisfaction was shown. It was expressed in violent criticism in a debate in the Chamber on March 26 by Franklin-Bouillon, president of the Foreign Affairs Committee; by the Budget Committee of the Chamber, which expressed to Clemenceau its regret that he did not intend to communicate the peace terms to the Chamber until after their signature, and that while the country was in a situation without any precedent Parliament should thus be confronted with a *fait accompli*, and should have no other method of expressing its opinion of the peace than by accepting it or rejecting it in all its clauses; and by the Senate, where an unofficial manifesto was signed by every member present, reminding Clemenceau of what France expected to find in the Treaty of Peace. At the same time, the Confédération Générale du Travail had placarded Paris and the provinces with a vigorous protest against what it termed the *sabotage* of peace.

*Internal French Situation.*—Clemenceau's strength as a war fighter and his pertinacity as a negotiator of peace, cannot be denied. Neither can the failure of his administration to cope with current economic and labour questions be disputed. From the start of his Ministry the more or less Draconian decrees as to food restrictions were not applied in the spirit in which they were drawn up. The Food Minister, Vilgrain, opened a number of State stores for the sale of groceries and other food-stuffs, but was unable by this method to make any impression upon prices. A bill was introduced on Feb. 5, inflicting drastic penalties upon speculative profiteering, but that measure also remained without effect. A hundred municipal butchers' shops were opened, but they also failed to stem the rising tide. These economic factors, together with political aspirations aroused by the course of events in Russia, led to a number of labour disturbances during the first four months of the Peace Conference.

Clemenceau was never a popular figure with Labour; his action in suppressing strikes had been far too vigorous for the workman's taste. They were therefore all the more surprised when, on Jan. 1, Clemenceau received the syndicalist delegates and asked the Confédération Générale du Travail to submit to him their economic demands, so that he might communicate those which were ripe for discussion to the Peace Conference. The moderate leaders, however, who were quite willing to accept this offered coöperation of Clemenceau, were unable to control the rank and file movement which led to a transport strike in Paris on Jan. 24, which brought to a standstill nearly all the city's methods of communication. Claveille immediately placed those services under military control, and the next day work was again resumed. On Jan. 27 there was further trouble on the P.L.M. system where a one-minute strike was called by the local executive.

The acquittal of Villain on March 30 for the assassination of Jaurès gave to Labour's economic discontent a political impetus, and in spite of the introduction of an eight-hour-day bill by M. Colliard, Minister of Labour, on April 8 Labour remained sulky. The bill was adopted after three days' discussion, on April 18. In spite of this and other indications of the conciliatory attitude

of the Government toward Labour, the extremists pressed forward with their plans for an unusually impressive Labour Day demonstration which as it happened to be but a day or two after the arrival of the peace delegates at Versailles, the authorities determined should be either peaceful or suppressed with the utmost vigour. Workmen employed in the following trades decided to come out: metal, building, shipbuilding, arsenals, miners, seamen, transports, dressmaking, theatres, concerts, municipal services. The postal and telegraph services only opened at 10 in the morning, and telephone operators struck for half an hour in the morning and half an hour in the evening. Electricians struck for 2 hours. It was at first decided to hold no public demonstration and to restrict the programme to a series of private meetings. At the last moment, however, it was decided to march in procession from the Place de la Concorde to the Place de la République. The Government issued a prohibition of any such demonstration, and troops were massed round Paris.

The day ended with rioting of a serious nature. There were a number of casualties on both sides, and as a result of the vigour with which the Government maintained its authority, M. Jouvaux, secretary of the General Confederation of Labour, resigned his position as a supplementary Labour delegate to the Peace Conference, and two other Socialists holding Government positions, M. Bouisson, Commissioner for Merchant Marine, and Compère-Morel, Commissioner for Agriculture, left their posts. The feeling left among the working-classes was one of great bitterness, and leaders did not accept their defeat. During the next two months strike after strike occurred, affecting all sorts of people from bank clerks and milliners to railwaymen and miners. It would be impossible to give any one reason for this discontent, which was due to both economic and political causes. The main factor of the first was the high cost of living, and of the second the faulty application of the ill-considered eight-hour-day bill, which led to a great amount of dispute in its interpretation, and with some piece-workers to a reduction of wages. In many cases the Confédération Générale du Travail found itself powerless to control the rank and file, who were inflamed by revolutionary propaganda, and by the circulation of quite unjustified statements that the Government intended to send large numbers of French troops to fight against the Russians.

These partial strikes continued throughout June, and the General Labour Federation decided, in unity with Italian labour, to proclaim a 24 hours' general strike in France on July 21. This strike was to be "a formidable warning to cease all armed intervention in Russia; to demobilize rapidly and without restriction; to reëstablish constitutional liberties; and to grant full and entire amnesty." It was also to be considered as a declaration of war upon the high cost of living. This move met with such faint-hearted support from Labour itself, and aroused such violent protest from the rest of the community, that on July 20 the C.G.T. decided to abandon its action. They had the satisfaction, however, of seeing a defeat inflicted on the Government two days before that decision was arrived at. This adverse vote was taken on a question of food policy, and the Food Controller, M. Boret, resigned. Clemenceau appointed Noulens to succeed him, and again managed to obtain a majority.

*Peace Treaty Criticism.*—The text of the Peace Treaty, and of the Franco-British and Franco-American Conventions accompanying it, was tabled at the Chamber of Deputies on June 30. The Chamber at once nominated a Peace Committee to report upon the document, M. Barthou being elected its president. His report was submitted to the Peace Committee on Aug. 5. It recommended the ratification of the Treaty, but drew attention to some of the provisions for ensuring French security on the Rhine, pointing out that their application would call for constant vigilance. He also criticized the exclusion from the pact of the League of Nations of those clauses proposed by France with a view to increasing the safety of her Eastern frontier. There naturally could be no question of a rejection of the Treaty; but its reception by Parliament was lukewarm. Parliament felt that it had not been allowed to play a proper part in the deliberations which had produced the document, and certain sections, notably the Right, were critical of the clauses dealing with the left bank of the Rhine and reparations. Tardieu, replying for the Government on Sept. 3, in the debate upon that report, outlined arguments which he subsequently developed at greater length in his book *La Paix*. The debates of that summer were academic or, at the most, preliminary to the storm of criticism which Clemenceau's work subsequently aroused. The Opposition had failed to upset the Government on economic questions; it was impossible for national reasons to try to do so on the Peace Treaty, and the House accepted the idea that Clemenceau would remain in power to "make" the approaching elections. The treaty was ratified by 372 votes against 52. There were 73 abstentions.

*Elections of 1919.*—On Oct. 2 a General Election bill was tabled in the Chamber fixing the dates for the elections as follows: —Chamber of Deputies, Nov. 16; Municipal Councils, Nov. 23; Mayoralty, Dec. 7; Councils General, Dec. 14; Senate, Jan. 11 1920. At the beginning of Nov. Clemenceau, speaking in Strassburg, made a programme speech which served as the rallying-ground for the widely diverse elements composing the *bloc national*. He made a fine appeal to all Frenchmen to realize that upon them depended whether they would in labour and tranquillity reap the benefits of the peace they had won. He dwelt upon the necessity for stable government, based on a large and solid majority; and his electioneering cry he found in Bolshevism, which had, indeed, made considerable progress, but, as was shown by the result of the elections, was far from being a national danger. The elections were fought with some bitterness, especially in the Seine, where Millerand and Barrès were the chief candidates of the *bloc national*, and where Longuet, the leader of the Socialists, figured on a list with Capt. Sadoul, a French officer serving with the Bolshevist army, who had been condemned to death by French court-martial for treason. The *bloc national*, comprising the moderate elements of the Chamber, and many of the extreme Conservatives, swept the country. The results of the elections were:—Conservatives and Liberal Action, 111 (a gain of 46); Progressives, 125 (a gain of 75); Left Republicans, 139 (a gain of 43); Radicals and Socialist-Radicals, 247 (a loss of 102); Socialist Republicans, 34 (a loss of 3); Unified and Dissident Socialists, 70 (a loss of 35).

*Presidential Election: Resignation of Clemenceau.*—This new Chamber met on Dec. 8, when it gave a welcome to the 24 deputies elected for Alsace-Lorraine. On Dec. 18 M. Deschanel was reëlected to the presidency of the Chamber by 478 votes out of 505. The Minister of Finance tabled two bills, one authorizing an additional credit amounting to 43 million sterling for the financial year 1919, and the other a vote on account for the first three months of 1920. The most important immediate business before Parliament was to proceed with the election of a successor to M. Poincaré in the presidency of the republic. Clemenceau, although not anxious to fill that office, was nevertheless prepared to accept it as the result of a more or less unanimous vote. The election of Deschanel to the presidency of the Chamber gave Clemenceau's opponents an opportunity of urging Deschanel to stand, and both he and Clemenceau agreed to abide by the decision of the preliminary meeting of the Republican groups of the Chamber and the Senate. Clemenceau was narrowly defeated in this party ballot, and withdrew his candidature. M. Deschanel was elected President in the National Assembly at Versailles on Jan. 17 1920 by 734 votes out of the 888 cast. Clemenceau placed the resignation of his Ministry in the hands of the President of the republic on Jan. 18 and retired into private life. Millerand, who had taken the chief part in organizing the parliamentary elections, formed a Cabinet as follows:—Millerand, prime minister and Minister for Foreign Affairs; L'Hopiteau, Minister of Justice; Steeg, Interior; François Marsal, Finance; Ledèvre, War; Landry, Navy; Honnorat, Public Instruction and Fine Arts; Le Trocquer, Public Works and Transport; Ricard, Agriculture; Isaac, Commerce, Industry, Posts and Telegraphs; Sarraut, Colonies; Jourdain, Labour; Ogier, Liberated Regions; Maginot, Pensions and War Allowances; Breton, Hygiene.

The new President was installed in office on Feb. 18, and two days later M. Poincaré was appointed president of the Repara-

tions Commission. The last days of Feb. a strike starting on the P.L.M. was extended by a miners' strike in the northern coal-fields. Both movements were due to the high cost of living. These partial strikes were very largely test movements organized in a more or less underground manner, without the full approval of the C.G.T. in whose directing committee Communists were struggling to obtain the ascendancy. May-day passed quietly, but was followed by a series of strikes ordered by the C.G.T. The programme of action which was then put forward showed that the Communists had carried the day. It included the formation of a national economic committee for the reorganization of production; the constitution of an international syndicate for the distribution of raw material; and the formation of an international fleet with a view to the regulation of freights; control of imports; reorganization of rail transport; international distribution of war burdens; the stoppage of Colonial expeditions; and disarmament. The seamen, dockers and miners were called out in support of the railwaymen. The strike was never popular, and the Government's action in arresting leaders was well supported by the public. On May 9 the C.G.T. mobilized more strikers, calling out the metal-workers, builders, underground railway and omnibus employees, aeroplane-workers, and all dockers. By that date the defeat of the strike was certain. Men were breaking away in very large numbers from their unions, and in spite of terrorism were returning to work. Evidence having been obtained of Russian participation in the movement, a large number of arrests was made. On May 21 the C.G.T. decided by 96 votes to 11 to admit defeat, and work was resumed on the following morning. The defeat was the worst ever inflicted on a big Labour organization, and it was calculated that over half a million members were lost by the extremist nature of the action.

*Millerand and the Presidency.*—No sooner was this crisis over than the Government was faced with one of an unusual and perplexing nature. M. Deschanel, President of the republic, while travelling by night to Montbrison, fell from the window of his compartment on to the track while the train was travelling at a good speed. No one noticed the accident, and it was not until Montargis was reached the next morning that the absence of the President was discovered. M. Deschanel was fortunate in not being seriously injured in his fall, but the shock, together with the effect of months, if not years, of life at high pressure, made it impossible for him to resume his functions. By the middle of Sept. after a further relapse, it became clear that he would have to resign his office. This was done formally on Sept. 16.

The course of events during the period which elapsed between Deschanel's accident and his resignation, was such as to favour the candidature of M. Millerand to the presidency. The prime minister's handling of Labour troubles had given him a great hold upon the Chamber; and although the growing friction with Britain and Millerand's attitude towards peace problems both roused discomfort in Parliament, the trend of events, especially after the Spa conference and the brilliant success of the French aid given to the Polish army in Aug., more than made good any gaps in his prestige. He accepted candidature, after issuing a statement that if he were sent to the Élysée he would pursue the policy he had advocated as prime minister. M. Millerand's action in boldly stating a programme shocked constitutional purists among the revolutionaries. After his election on Sept. 23, when he obtained 695 out of 892 votes, Millerand explained in further detail that he intended to play a larger part than had hitherto been taken by presidents of the republic in the field of foreign affairs; and that he contemplated constitutional reform the tendency of which would be to increase the usefulness of his office. The ministerial crisis resulting from this change in the presidency was settled by M. Georges Leygues stepping into Millerand's vacant place, the Cabinet remaining otherwise unchanged.

The new Government's statement of policy was naturally approved after a very brief debate. At the same sitting a presidential message was read, in which Millerand again referred to the advisability of constitutional reform, and dwelt upon his intention to act as guardian in the application of the Versailles Peace Treaty. André Lefèvre, the Minister of War, resigned his office on Dec. 16, in order to have his hands free to press for the rigorous disarmament of Germany. He was succeeded by M. Raiberti, president of the Finance Committee of the Chamber.

This Ministry of M. Leygues was never intended to be anything but a stop-gap. It enabled Millerand to get his feet into the stirrups without receiving too much advice as to how to ride the horse of state from former presidents or prime ministers. M. Leygues' chief task was to follow closely the lines laid down for him by M. Millerand in the various meetings which were still taking place with regard to peace between allied statesmen. He fell from power at precisely the moment when it seemed fit that M. Briand should take the reins. This he did in the middle of Jan. 1921. His chief concern was Franco-British relations, which, ever since the Armistice, had been drifting into troubled waters.

*Franco-British Relations, 1919–21.*—With the disappearance of Germany as a world-power, it could not but be that a principal factor in the Franco-British Entente had ceased to exist. Even during the war, in meetings between statesmen and soldiers of the two countries, there were many differences of opinion. Yet, when the Armistice was signed, relations between the two countries were excellent. It was inevitable, however, that in the sharp exchange of views at the Peace Conference, when not only the vital interests of the moment but also the far-distant future of nations was at stake, individual interests should tend to supplant the common sacrifice of war-days. French public opinion, when it studied the conditions of peace, became persuaded that in the Peace Conference the British delegation, and Mr. Lloyd George in particular, were there not so much as statesmen settling the world's affairs from the high mountain of humanity, but as political travellers who had to show results to the house which employed them. This French point of view is stated here without the criticisms, comments and corrections, which might be aroused by it. There were two great crises during the Paris Peace Conference, and the solution accepted by Clemenceau in each case formed the subject not only of diplomatic action and discussion abroad, but of political agitation and criticism in the French Parliament itself. They were due to marked divergencies of views between France and Great Britain as to the future of the left bank of the Rhine, the Saar Valley, and reparations. In the discussion of these three questions two main tendencies soon became apparent. Mr. Lloyd George, according to André Tardieu, was anxious lest the conditions to be imposed upon Germany would be such as would lead her to refuse to sign. This anxiety and the dread of the possible extension of Bolshevism throughout Europe found their most direct expression in a memoir Mr. Lloyd George drafted on March 26 1919, in which he enjoined moderation upon himself and upon his allies. To this memorandum the French Government replied that it was in complete agreement with Mr. Lloyd George in desiring to make a lasting and therefore a just peace, but that it did not think that, by softening down the European territorial clauses, his object would be obtained. It pointed out that the great war for Germany had not been a European war but a world war; that all her colonies, all her navy, a large portion of her merchant fleet, and her foreign markets were to be taken from her. It was these clauses which would hurt her, and it was an illusion to believe that she would be soothed by giving to her better European territorial conditions. The Note drew the attention of the British Government to the fact that if its suggestions were accepted a certain number of complete and definite guarantees would be given to maritime nations which had not suffered from invasion, such as Great Britain; for instance, the cession of the German colonies, the handing over of the German war fleet; the surrender of a large part of Germany's merchant marine, and for a time, the exclusion of Germany from foreign markets. To continental countries, on the other hand, to those which had most suffered from the war, partial and limited solutions of their difficulties were offered, such as the reduced frontiers of Poland and Bohemia, the limited defensive undertaking with regard to the protection of France, and the limited exploitation of the Saar coal-fields. With a foresight justified by subsequent events, M. Tardieu, who drafted this Note, pointed out that the inequality of the proposed solutions would be likely

to have detrimental effects upon Inter-Allied relations after the war. On the points thus detailed, however, compromise agreements were reached during April 1919, and the text of the Treaty was handed to the Germans on May 7.

It was after that date, on May 25, that a second crisis broke out. It lasted until June 16. All Mr. Lloyd George's fears as to the probability of the Germans refusing to sign the Treaty had been reawakened, and he suggested a number of concessions on such questions as disarmament, the occupation of the Rhine, reparations, Dantzig and Silesia. It required a very determined effort on the part of the French peace delegation to prevent a last-hour revision of the terms. The settlement of the question of the left bank of the Rhine undoubtedly caused the most perturbation among French politicians. Marshal Foch on Nov. 27 1918, and again on Jan. 10 1919, had urged that, for the security of France, the Rhine must become the western military frontier of Germany, and that that nation should be deprived of the military spring-board on the left bank she had used with such effect in 1914. This proposal had been discussed in March and refused by Great Britain, and instead of the occupation and independence of the left bank, Great Britain and the United States offered the military guarantee against any aggression on the part of Germany, the undertaking of Great Britain being dependent upon American ratification of that agreement. This was not forthcoming. Clemenceau, after a hard fight, succeeded in inserting in the Peace Treaty a clause to the effect that if, within 15 years—the period of occupation laid down in the Treaty—Germany had not fulfilled her engagements, that period could be prolonged. There were many Frenchmen, and notably Marshal Foch, who refused to see in this compromise a sufficient safeguard for French frontiers, or for the execution of the Treaty of Versailles. Their number naturally grew when the American Senate refused to ratify the Treaty, and not only the American but the British undertaking to give military aid to France, were she attacked by Germany, fell to the ground.

In the treatment of the problem of the Saar coal-fields and of reparations, the French also thought that Lloyd George looked exclusively to British interests. Great though the criticisms were against the Treaty of Versailles, they were as nothing compared with the resentment aroused in France by the application of that Treaty by Great Britain. The coal agreement at Spa, which made France pay heavily to the British Government for her coal, the British encouragement of the Emir Faisal and other elements in the Middle East which were regarded by the French as antagonistic, the British negotiations for the resumption of trade with Bolshevist Russia, the anti-Polish attitude of the British Government during the Peace Conference over the Dantzig Corridor, and afterwards during the Polish-Bolshevist War, the intransigent attitude adopted in favour of Greece and against the Turkish Nationalists—all contributed towards disagreement between France and Great Britain.

These were French criticisms, and represented French causes for dissatisfaction with British policy after the Armistice. An equal number of British complaints against French policy could undoubtedly be found. The result was that in 1920 and 1921 a good deal of diplomatic friction was occasioned from time to time; and it was renewed in Dec. 1921 as the result of the French attitude towards disarmament at the Washington Conference. But it was clearly in the predominant interests of both Great Britain and France that they should bring their respective peace policies into agreement, and march forward hand in hand. The moment was perhaps not ripe for a formal alliance, but in 1921 there were influential people on both sides, and in England notably Lord Derby, who were working towards a restoration of completely cordial relations between France and England, in preparation for a definite understanding which might form the foundation of permanent peace in Europe. (G. A.)

**FRANCIS FERDINAND** (FRANZ FERDINAND VON ESTE) (1863–1914), Archduke of Austria, was born at Graz Dec. 18 1863. His father was the Archduke Charles Louis, second of the younger brothers of the Emperor Francis Joseph; his mother was the Princess Maria Annunciata, daughter of the Bourbon King Ferdinand II. of the Two Sicilies. His mother died while he was a child, but he was affectionately cared for by his father's second wife, Maria Theresa of Braganza, daughter of the exiled Portuguese Prince Dom Miguel of Braganza. He received the education usually given to members of the imperial family, not too thorough a one, as his succession to the throne was not anticipated. In later years, when he had become heir to the throne, Francis Ferdinand worked with iron industry to fill in the gaps in his education; he learned the languages of the nations over whom he appeared to be called to rule, and took pleasure in obtaining instruction from leading men of science in their special branches of knowledge. He showed special interest in the natural sciences and in the plastic and pictorial arts, but had little taste for poetry and music.

When the education prescribed for him was completed Francis Ferdinand, still following the archducal tradition, entered the army, which kept him for many years away from the imperial palace. In 1875 he took the name of Austria-Este, as heir of his uncle the Duke of Modena, with whose death the male line of this branch of the house became extinct, and of his possessions in Austria-Hungary and Italy. Until the death on Jan. 30 1889 of the Crown Prince Rudolf, Francis Ferdinand was only known in limited circles, and even then he did not at first play any prominent part. For although his father, the next heir to the throne, showed little inclination to make use of his rights when occasion offered, his uncle the Emperor did not give Francis Ferdinand any share in the business of government. He devoted himself as before to his military duties and to the management of his extensive estates. In 1892–3 he made a world tour, which he described in two volumes issued in 1895. He himself states the chief aim of his travels to have been the satisfaction of his desire to become acquainted with foreign systems of government, and to get into touch with foreign peoples and persons and foreign manners and customs. But his delight in the adventures of the chase—he was an excellent sportsman and an admirable shot—his strongly developed feeling for nature, and the desire of his friends and relations to strengthen the uncertain health of a prince born of a consumptive mother counted among the reasons for the long journey. The last aim was not realized; Francis Ferdinand's sufferings notably increased after his return, and compelled him, after his father's death in May 1906 had made him heir-apparent to the throne, to spend considerable periods in southern resorts. The undisguised haste with which many people, especially those connected with the court, who had hitherto courted him, deserted him, now that he was seriously ill and his succession improbable, hardened the prince's character, which was not naturally gentle, increased his distrust of the men who surrounded him, and heightened his contempt for mankind.

When his health improved he returned home and spent a considerable time very actively on his estate at Konopischt, where he established a model farm and gained the reputation of a close-fisted and not very popular master. Even then he was not invited by Francis Joseph to take part in state affairs; yet the Emperor frequently commissioned him to represent him abroad, and gradually allowed him to exercise greater influence in military matters. In 1896 Francis Ferdinand became a cavalry general, and on April 1 1898 he was placed at the disposition of the supreme army command; in 1902 he became an admiral of the Austro-Hungarian fleet. Learned bodies and artistic societies gave him their highest places of honour. He became honorary member and later curator of the Imperial Academy of Science at Vienna and patron of the Academies of Science in Prague and Cracow.

On July 1 1900 Francis Ferdinand married Countess Sophie Chotek (1868–1914), after having overcome by tenacious persistence the obstacle due to the fact that the lady was not of royal family, and renounced, a few days before the ceremony, the succession rights of any children of the union. This renunciation was not only inscribed in the records of the imperial family, but ratified in the Austrian and Hungarian Parliaments and sanctioned by a law of Dec. 4 1900. The consort of the heir to the throne was raised to princely rank with the title of Hohenberg; later on she received the rank of duchess with the style of

"highness." Of this marriage were born a daughter, Sophia (b. 1901), and two sons, Max (b. 1902) and Ernest (b. 1904). The influence of his ambitious, clever, rigidly Catholic wife on the heir to the throne was lasting. The difficulty of providing her with a position at Court corresponding with his own and her desires estranged him from the majority of the members of the imperial house, and influenced unfavourably his relations with Francis Joseph, with whom he had never really been on intimate terms. Still his influence increased as years went on; the Emperor gradually allotted to him responsibilities of his own, not only in military matters but occasionally in questions of domestic politics. Yet until Francis Ferdinand's death the Emperor reserved for himself the final decision in every question which arose. The difference of outlook of the two men became more and more marked; for with advancing age Francis Joseph was less and less willing to consider far-reaching reforms, was anxious to avoid any conflict with the nationalities, and preferred advisers who knew how to untie a knot gently instead of hacking through it. It is not surprising that he did not like Francis Ferdinand, who advised rapid and energetic action and, if necessary, methods of violence. So it happened that the nephew did not take into sufficient consideration the jealousy with which his aged uncle guarded his rights as a ruler; he repeatedly spoke of the responsibility which God had imposed on him with his right of succession; he would express a curt opinion on men and things when he knew that they did not correspond with the view of the sovereign. The estrangement increased; personal contact became rarer; Francis Ferdinand came into the Emperor's presence only on exceptional occasions; as a rule he contented himself with expressing his views in writing, and they very rarely agreed with his uncle's. For Francis Ferdinand was decidedly opposed to the preponderant influence exercised in ever-increasing measure by the Magyars in both the domestic and the foreign affairs of the Dual Monarchy, and blamed the complaisance shown by Francis Joseph to all Hungarian demands which did not directly threaten the unity of the monarchy or seriously menace the rights of the throne. Francis Ferdinand was convinced that this Magyar preponderance must be broken in the interests of the monarchy and the dynasty. As to the way in which this struggle was to be conducted his opinion varied from time to time. For some time he was wholly in the camp of the Federalists, and directed his efforts to the splitting-up of the monarchy into a series of states possessing equal rights and held together by a strong central Government. At another period, especially just before the first Serbian crisis, he inclined to "Trialism" as the best solution. At that period he contemplated the union of the Southern Slavs as an independent state within the Habsburg dominions, but abandoned this scheme when he realized that the union of the Austrian and Hungarian Slavs in a separate national system would merely forward the intentions of the Belgrade Government. Later, strongly influenced by the Hungarian minister Kristoffy, he inclined to the idea of attempting, by a change which would leave the dualism of the monarchy as such untouched, to strengthen unity by changing the Delegations into a central Parliament and attaching the annexed provinces Bosnia and Herzegovina, with a state organization of their own, to the Empire. The opposition which he met on all sides from the ruling party in Hungary strengthened his conviction that here lay the essential obstacle to the healthy recovery of the monarchy. In the severe conflicts between the Magyars and the Crown from the beginning of the 20th century onwards he, therefore, maintained the opinion that no concession must be made, and that there should be no shrinking even from the use of armed force for the defence of the rights of the monarchy and the dynasty. The conclusion of the struggle, after a duration of more than five years, in a compromise was a bitter disappointment to Francis Ferdinand, and strengthened his dislike for the Magyar leaders, among whom he particularly hated Stephen Tisza, whose high standing he recognized.

He was more successful in his opposition to the Magyar attempts for the partition of the army. In this, as in the questions of the language to be used in the words of command and response, and of the regimental colours and emblems, he had the Emperor's support, and was able to hinder the accomplishment of the Magyar desires.

The zeal with which Francis Ferdinand sought for the solution of domestic political problems by strengthening the central power is explained by his firm conviction that this was the indispensable condition of the position of the monarchy as a Great Power, which he desired to maintain and to increase. Francis Ferdinand was not an unconditional adherent of the group which thought his aim would only be attained by force of arms. He repeatedly foiled their intentions. But he was firmly determined to tread this path if it was the only one by which the goal could be reached. Personal inclination and a conviction of the commanding position of Great Britain made him regard the establishment of good relations with that Power as desirable. Towards the French, and still more towards the Italians, his attitude was cool and negative. He was convinced that it was impossible to establish permanently friendly relations with the Italian nation, and that there must inevitably be a day of reckoning between the monarchy and Italy. He never adopted an anti-Slav policy. Not only did he wish, from the point of view of his plans for internal reconstruction, to avoid conflicts with the principal representatives of the Slav nationalities, but he recognized in the Tsar of Russia the strongest support against revolutionary movements in monarchical states. Nor is it true that he wanted to see Serbia struck out of the list of independent Balkan states; he merely expressed the decided opinion that the encroachments of the Greater Serbia movement on Austro-Hungarian soil should be resisted with all the forces of the monarchy. He stood faithfully by Germany, with whose ruler his relations became more and more intimate, in spite of the difference between the characters of the two men. Yet no one was less inclined to contemplate the monarchy falling into a relation of dependence on her powerful ally than Francis Ferdinand, whose whole being was informed with a sense of the majesty of the Habsburg-Lorraine dynasty.

Francis Ferdinand was a man of more than average ability. He had a power of quick comprehension; possessed in a high degree the ability to recognize the essential point in any business in which he was engaged, and, unlike his uncle Francis Joseph, did not allow his general impressions to be clouded by too close attention to detail. What he lacked was knowledge of men, calmness and constancy in his relations with the men who had been placed in high offices of state by his influence: Beck, Aehrenthal, Conrad, Auffenberg and others lost, not always for any serious reason, the favour of the heir to the throne as quickly as they had won it. The influence of his wife, ill-natured tittle-tattle to which he listened more and more, and the outbursts of ungovernable rage to which he became increasingly prone with the years, all helped to make intercourse with him more difficult, and prevented a great many persons holding high positions, socially and intellectually, from approaching him. He never enjoyed any wide popularity, and indeed did not seek it.

He asked from the citizens of the monarchy not affection, but submission to the will of the ruler. For to him the State was identified with the divinely appointed person of the monarch. He understood by *viribus unitis* the union of all the forces of the State for the advantage of the Crown, which on its side had to guard the interests of all. This conception accounts for the fact that he took no particular interest in any of the numerous nationalities of the monarchy. He had undoubtedly German sympathies; but the German Austrians were to him merely the bulwark of the throne and of the power of his House; it would never have occurred to him to make dynastic sacrifices for their sake. Even against the Catholic Church, of which he was a convinced adherent, he maintained the rights of the throne with unbending severity, being in this matter also a true Habsburg.

His tragic end—he was shot June 28 1914 with his wife by Bosnians of Serbian nationality at Serajevo—brought on the World War.

There is no proper historical account of his life and activities. The sketch, *Erzherzog Franz Ferdinand, unser Thronfolger*, a special number of the *Oesterreichische Rundschau* (1913), is purely super-

ficial. His descent is given in *Ahnentafel S. k. H. des durchl. Herrn Erzherzogs Franz Ferdinand von Oesterreich-Este*, drawn up by Otto Forst (1910). See also Paul von Falkenegg, *Erzherzog Franz Ferdinand von Oesterreich-Este* (1908); H. Heller, *Franz Ferdinand* (1911). (A. F. Pr.)

**FRANCIS JOSEPH I.** (1830–1916), Emperor of Austria and King of Hungary (*see* 10.942*).—In the last years of his reign Francis Joseph continued to strive to preserve peace for his realm, while maintaining the prestige of Austria-Hungary and her position as a Great Power. Perceiving that this aim was threatened by the confusion reigning in the Balkans, he agreed to the plan of his Foreign Minister, Aehrenthal, to take advantage of the Young Turk movement to annex the territories of Bosnia and Herzegovina occupied in 1878, and to embody them permanently in the monarchy. During the serious crisis following on the annexation Francis Joseph backed Aehrenthal with the whole weight of his influence, and subsequently supported him in his endeavours to restore friendly relations with the Great Powers which had been signally disturbed by the annexation, and to put an end to the risk of international conflicts. By his personal intervention he in fact repeatedly succeeded during the years 1908 to 1914 in averting dangers threatening the peace of Europe. When in 1912 the Balkan wars, which he had untiringly but unsuccessfully striven to avert, began, he thought they were the gale before the hurricane, and when, in Aug. 1913, the Peace of Bucharest provided a provisional settlement he expressed the opinion that this peace was only the breathing space before a fresh war. The behaviour of the Serbs filled him with the greatest anxiety. When the murder of the heir to the throne, the Archduke Francis Ferdinand, led the Vienna Government to take energetic measures against Serbia, Francis Joseph hesitated to follow, and it was with a heavy heart that he gave his consent to the dispatch of the severe ultimatum to Serbia, and, after its rejection, to the declaration of war. He did not believe that the war could be localized, as he would have wished it to be, and was pessimistic about the chances of a world war. Even then he was of the opinion that "war is beyond our strength," and said he would be glad if the monarchy escaped "with a black eye." The attitude of the rulers of Italy and Rumania offended him deeply, and strengthened his doubt of a favourable outcome of a war against an ever-increasing number of adversaries. Francis Joseph stood immovably by the alliance with Germany, to whose ruler he was bound by a friendship based on reciprocal liking; it never occurred to him to separate from his ally. He would never have agreed to a separate peace; yet he favoured and supported every endeavour to put an end to the war by a peace which should safeguard the interests of all his allies and the position of Austria-Hungary as a Great Power.

In all questions affecting the constitution of the monarchy, and in particular the relations between Austria and Hungary, Francis Joseph continued in the later years of his reign to stand by the principles of the *Ausgleich* of 1867. He would not consider the federalization of the Empire, but stood unmoved on the basis of dualism. He went a long way to meet the efforts of the Hungarian Government for independence, but refused energetically during this period demands tending towards the severing of the remaining bonds between the two halves of the monarchy, especially that of the united army. In the increasingly violent conflicts between the different nationalities inhabiting the Cis-Leithan territories Francis Joseph stood above party. This was all the easier for him on account of his indifference towards all the nationalities of his vast realm, even towards the Germans, although to the end of his life he felt himself to be a German prince. As in the earlier part of his reign, so in the last decade, the separate nationalities were favoured or neglected, but always played off one against the other. The meaning of *viribus unitis* for Francis Joseph was to use all in the interests of the dynasty. But national consciousness had grown so strong that this policy had no success. The concessions which he granted in the years just before the war to the Slav peoples increased their self-confidence, and led them to make ever greater demands, the non-fulfilment of which caused a weakening of their sentiment for the dynasty. As the differences between the national parties represented in the Austrian Parliament became in the course of years so great that there was no prospect of effective coöperation, Francis Joseph ignored parliamentary activity from 1914 onwards. Experience of the World War led the old Emperor to recognize that he had done the Austrian-Germans an injustice; but isolated attempts to alter the trend of affairs had no lasting effect, and in the end he let things take their course. When he died, severe inroads had been made on the affection of the Austrian peoples; what remained was only just sufficient to disguise the disappearance of loyalty to the dynasty.

As years went on the Emperor became more and more lonely. His son had committed suicide in 1889, his wife had been murdered in 1898; of his brothers only the youngest was still alive, and he resided at a distance and in the strictest seclusion. There had never been any cordial relationship with the heir to the throne, Francis Ferdinand; and with the years, especially after Francis Ferdinand had married Countess Sophie Chotek, the estrangement between the two men increased, so that personal intercourse became rare. Among the remaining members of the Imperial House Francis Joseph only cared to frequent the circles of his two daughters, Gisela and Marie Valerie, and their children. He was bound by ties of true friendship to Katherina Schratt, formerly an actress at the Burgtheater, and in her society he spent his sparingly measured hours of recreation. The summer he usually spent at the watering place of Ischl, and there he devoted himself to the chase, the only pleasure for which he cared passionately to the end of his life.

The Emperor had long enjoyed excellent health. It was not until he had passed his 75th year that disease of the respiratory organs began. In 1911 this became so serious that a catastrophe was feared. All the preparations for Francis Ferdinand's accession were made. But the old Emperor recovered; and his physical as well as his mental energy improved from year to year, so that he was able in the first two years of the World War to transact fully all the business of government. It was only in the year 1916 that his faculties began to fail. He died peacefully of a fresh attack of his old malady on Nov. 21 1916.

Francis Joseph was not one of those of whom contemporaries, especially those at a distance, form any definite impression. The reserve which he observed even towards the great majority of his advisers made it more difficult to penetrate his real nature. He had a deep sense of his exalted position as a ruler. To the end of his days he remained profoundly convinced that the Empire over which he ruled was *his* empire, and the peoples *his* peoples. This conception of the majesty of the office bestowed on him by God found expression in his bearing. He always maintained a regal attitude. He showed kindliness and winning courtesy to everyone. Nothing was farther from him than posing, and no one ever heard him utter sonorous phrases; but he avoided any kind of intimacy even in his intercourse with members of the Imperial House, and, even with them, knew how to maintain his distance. His intellectual gifts were not remarkable, but he possessed sound common-sense and wit. He had a strikingly good memory for persons and events. As a ruler he was a model of the sense of duty. From early morning to evening he attended to business with clock-like regularity, and dealt with all the documents laid before him with the greatest punctuality. This industry and his exact memory made him one of the best authorities in all Government affairs. He sometimes startled his ministers by his intimate knowledge of the details of the business in hand, and occasionally embarrassed them. But he went no further than the details, and lacked the power of surveying the whole. He also lacked, especially in his later years, the ability to take the initiative in important questions, to form independent resolutions and to carry them to their logical conclusions. In an ever-increasing degree he left the decision to his responsible ministers. He was not without skill in the choice of his advisers, but had an instinctive dislike for men whom he felt to be his intellectual superiors. He also disliked people of proud and upright character, and even within the family circle he preferred those who were more subservient. He was essentially cold in tempera-

* *These figures indicate the volume and page number of the previous article.*

ient, with great self-control increased by practice. Among the European rulers he enjoyed, during the last decades of his reign, reat respect, which he owed to his age, experience, personal inability, blameless conduct, and above all the fact that his ord could always be relied upon. He was a faithful son of the atholic Church, and looked up with reverence to the Holy ather; but, quite in the spirit of the traditions of his House, he uarded the rights of the dynasty and of the State with the tmost tenacity, even against the Pope. He took no interest in he arts and sciences, being in this respect more of a Lorrainer han a Habsburg; but whenever he expressed an opinion on hese subjects, he showed a decided aversion from the modern endencies.

It is not yet possible to give a complete picture of Francis Joseph's haracter, as the necessary references are not available. Up to 1921 ractically none of his correspondence had been published. For the eriod up to 1908 there is the elaborate publication *Francis Joseph* ., by different authors. His biography has been written by R. P. Mahaffy, *Francis Joseph* (1908); Baron Eugen d'Albon, *Vom Kaiser* 1909); Smolle, *Unser Kaiser* (1908). A successful attempt to draw sketch of the Emperor, based on information from ministers, enerals, and other officials who were in close touch with him, was ade by H. Friedjung under the title "Kaiser Franz Josef I." in *istorische Aufsätze* (1919, pp. 493 *seq.*). The numerous popular ublications which appeared soon after the death of Francis Joseph re of no historical value. The same is true of *Kaiser Franz Josef nd sein Hof, Erinnerungen und Schilderungen aus den nachgelassenen apieren eines persönlichen Ratgebers*, published and translated by .. Schneider (1919). (A. F. Pr.)

**FRASER, ALEXANDER CAMPBELL** (1819–1914), Scottish hilosopher (*see* 11.38), died at Edinburgh Dec. 2 1914.

**FRAZER, SIR JAMES GEORGE** (1854– ), British anhropologist, was born at Glasgow, Jan. 1 1854. Educated at Helensburgh, Glasgow University and Trinity College, Camridge, he was elected fellow of his college in 1879 and was called o the bar. In 1907 he was elected professor of social anthropolgy at Liverpool. His principal work, *The Golden Bough*, first ublished in 1890 (2nd ed. 1900) and reissued with enlargements in 12 vols. under seven titles between 1907 and 1915, was an laborate study of the Greek cults, their origins and their place n the comparative history of religion. He also published *Pauanias and other Greek sketches* (1900) and *Sir Roger de Coverley nd other literary pieces* (1920). His views on the connexion etween magic and mythology are explained in 19.133 and 17.305; hose on folklore are described in 10.601.

**FREDERICK,** Archduke of Austria, Duke of Teschen 1856– ), Austro-Hungarian field-marshal, was born at Gross-Seelowitz, Moravia, June 4 1856. Like most of the princes f the ruling house he adopted a military career, and served reditably for many years as commandant of the V. (Pressburg) Corps. Subsequently commander-in-chief of the Austrian Landwehr and army inspector, he became, after the murder of the eir to the throne, Archduke Francis Ferdinand, inspector-eneral at the head of the common Austro-Hungarian army. Archduke Frederick was possessed of a considerable fortune, nd was one of the greatest landowners in the monarchy; the Albertina Collection was among his inherited possessions. In he World War he was—from the dynastic point of view—as randson of the victor of Aspern, Archduke Charles, and as ephew of the victor of Custozza, Archduke Albert, the prelestined head of the armed forces of Austria-Hungary. He hought it his duty, to accept this heavy responsibility, but, nodestly estimating his own powers, left the actual exercise of he command to his chief-of-staff, Conrad von Hötzendorf. In the performance of ceremonial duties, and as mediator for the ettlement of the conflicting demands of the military, civil and llied elements, his services were undeniable. In the spring of 1917 Emperor Charles himself took over the supreme command; he Archduke, although the Emperor's representative, no longer ppeared in the foreground. He married, in 1878, Princess Isabella of Croy-Dülmen, and of this marriage there were eight laughters and one son, who served as an officer in the World War.

**FREDERICQ, PAUL** (1850–1920), Belgian historian, was born at Ghent, Aug. 12 1850, and was educated at the university of Liége, where he became professor of history, later (1883) occupying the same position at Ghent. His chief works were *Essai sur le rôle politique et social des ducs de Bourgogne dans les Pays-Bas* (1875) and *Corpus documentorum Inquisitionis hereticae pravitatis Neerlandicae* (1889–1906, 5 vols.), and many shorter studies, principally on the religious history of the 16th century and the history of the Flemish literature. He was a strong supporter of the Flemish movement, of which he wrote a history, *Schets eener Geschiedenis der Vlaamsche Beweegnig* (1906–9). On the invasion of Belgium by the Germans he was active in encouraging the patriotic feelings of his countrymen and urging every sort of moral resistance to the enemy, being in consequence deported to Germany (March 16 1916), in company with Prof. H. Pirenne. He was interned successively at Gütersloh, Jena and Bürgel. He returned to Belgium after the Armistice and was appointed rector of Ghent University. His imprisonment, however, had seriously weakened his health, and he died March 23 1920. He was a member of the Academie Royale de Belgique, the Commission Royale d'Histoire and the Academie des Pays-Bas, and his influence on the teaching of history in Belgium was profound. He was converted to Protestantism in his youth, and his tendencies in religion, as in politics, were liberal.

See Ch. Nyrop, *L'Arrestation des professeurs belges et l'Université de Gand* (Paris, 1917; also translated into English and Danish); V. Fris, *Les deux historiens nationaux exilés pour leur patriotisme* (1919). (H. P.)

**FRÉMIET, EMMANUEL** (1824–1910), French sculptor (*see* 11.96), died Sept. 11 1910.

**FRENCH, JOHN DENTON PINKSTONE FRENCH,** Earl (1852– ), British field-marshal, was born Sept. 28 1852. The son of a naval officer, he entered the Royal Navy, in which he served as cadet and midshipman from 1866 to 1870. Joining the militia he passed from this into the army in 1874 and was gazetted to the 19th Hussars. He married Eleanora, daughter of R. W. Selby Lowndes in 1880. He served in the Nile expedition in 1884–5, and commanded his regiment from 1889 to 1893. After two years on the War Office staff he commanded a cavalry brigade from 1897 to 1899, and on the mobilization of the expeditionary force for S. Africa in the latter year he was chosen to command the Cavalry Division and was promoted major-general. Pending the assembly of this, he served in Natal, where he commanded the troops on the field at Elandslaagte and took part in the early combats near Ladysmith, but he proceeded to Cape Colony just before the place was invested. After a few weeks in charge of the force at Colesberg, he led the cavalry during Lord Roberts' advance from Cape Colony, relieved Kimberley, cut off the retreat of Cronje's army, and occupied Bloemfontein. During the subsequent advance into the Transvaal he was in command of the left wing, and at a later stage of the victorious campaign he played a prominent part in the move from Pretoria to Komati Poort. For these services he was given the K.C.B. During most of the second phase of the struggle he was in command of the forces operating against the enemy in Cape Colony, and he was on the conclusion of hostilities promoted lieutenant-general and was given the K.C.M.G.

He commanded at Aldershot from 1902 to 1907, in which year he was promoted general, and he then became inspector-general of the Forces for five years. He was appointed chief of the Imperial General Staff in 1912 and was promoted field-marshal in 1913. In April 1914 he vacated the post of C.I.G.S., owing to military troubles in Ireland in connexion with Ulster, but four months later he was chosen to take charge of the Expeditionary Force on the outbreak of the World War, and he commanded the British army on the western front from the outset of the struggle until the end of 1915. The chief events in France while he was in command were the retreat from Mons under circumstances of great difficulty; the battle of the Marne and subsequent advance to the Aisne; the transfer of the Expeditionary Force to Flanders; the desperate fighting in the autumn, generally called the First Battle of Ypres; the successful Neuve Chapelle offensive undertaken in March 1915; the Second Battle of Ypres in April 1915;

the abortive operations near Festubert embarked on a few days later; and the important victory won in Sept. in the region of Loos. During the seventeen months that the field-marshal led the British troops in the field, these rose, excluding cavalry, from an original total of five divisions at the front to a total of 34 divisions; these he had organized as three armies. His forces up till the last three months suffered greatly from a lack of artillery ammunition, except during the opening weeks of the campaign; this hampered his operations to an extent not experienced by his successor. He resigned in Dec., Sir D. Haig taking his place, and he returned to England, to be raised to the peerage as Viscount French of Ypres and High Lake in recognition of his great services. He then became commander-in-chief in the United Kingdom, and he held that appointment until May 1918, when he was selected to be Lord-Lieutenant of Ireland. This position he occupied under most trying conditions until early in 1921, the political state of the country growing worse and worse. On resigning he was rewarded with an earldom.

At the end of the war, Lord French published his personal narrative under the title, "*1914*."

**FRENCH EQUATORIAL AFRICA** (*Afrique Equatoriale Française;* or *A.E.F.*), formerly FRENCH CONGO (*see* 11.99), is an immense region stretching from the mouth of the Congo to Tripoli, from the Atlantic to Egypt, covering an area of about 870,000 sq. miles. It is therefore more than four times the size of France. The coast is but little developed and is as a rule flat and sandy. There are few good ports. At a short distance from the Atlantic the country rises to a plateau between 2,300 and 2,700 ft. high, in which lies the vast depression of the closed basin of the Chad. The chief characteristic of the colony is its magnificent river system. It has the Congo for a distance of 370 m. of its course of 2,500 m., its great tributaries (the Sanga or Sangha and Ubangi), the Ogowe (801 m.), and the huge expanse of Lake Chad, which receives the water of the whole of the Schari and Logone valleys. In natural characteristics there are two clearly distinct zones—forest and brush. Tropical forest with luxuriant vegetation and intense animal life covers the Gabun and the valleys of the Sanga and Ubangi; brush reigns up to and beyond Lake Chad. The climate is extremely humid and painfully hot.

Estimates of the population range from 6 to 10 millions. Sleeping sickness is very prevalent. There are many different races and varied types among the natives, but two main groups can be recognized. There are the sedentary people of the forest zone who are very savage and occasionally cannibal, but can adapt themselves to agriculture, and the Nomad tribes of the brush country who are warlike herdsmen influenced by Islam.

A.E.F. is a colony of special growth. Its frontiers were laid down by diplomacy before the country had been explored. The main steps in French occupation of Equatorial Africa were:—(I.) Foundation of French Congo (1842–82), and the great exploration expeditions of de Brazza. (II.) The Berlin Conference and the General Act of 1889 which established international understanding with regard to freedom of navigation and trade in basins and mouths of the Congo and the Niger, and as to the formalities to be observed in order to make the fresh occupations of Africa effective. (III.) The period of political and diplomatic action over the Congo between 1889 and 1909, when a number of Boundary Conventions were signed. (IV.) French expansion towards the Upper Nile, which gave rise to the Fashoda incident (1898) and a declaration in 1899 in which the eastern limits of the French zone of influence in West Africa were laid down. (V.) French expansion in the Chad. The work of the great explorers Crampel, Maistre, Gentil and Maj. Lamy brought about the realization of the ambitious plan of linking up, through Lake Chad, the oases of Algeria and the shores of the Ubangi.

In 1911, following upon the Agadir incident, A.E.F. enabled France to compensate Germany for the rights she ceded to France in Morocco. The colony then lost nearly 100,000 sq. m. of territory, which was joined on to German Cameroon. This was restored by the Treaty of Versailles.

*Administration.*—A.E.F. is an amalgamation of four different colonies under a governor-general. This post was created by decree June 26 1908, and a further decree Jan. 15 1910 gave definite form to the new administration.

The Government General of French Equatorial Africa consists of the following colonies:—

Gabun (cap. Libreville) 104,000 sq. m. Middle Congo (cap. Brazzaville) 89,000 sq. m. Ubangi-Schari (cap. Bangi) 193,000 sq. m. Chad (March 17 1920) 482,000 sq. m.

The supreme administrative head is the governor-general who resides at Brazzaville. The different colonies preserve their administrative and financial autonomy and are governed by lieutenant-governors with the exception of the Chad, which has either a civil or a military administrator. A government council assists the governor-general, who has his delegates in Paris at the Office Colonial and at the Supreme Colonial Council.

*Colonisation.*—The policy pursued with regard to colonization of this vast country has not been very successful. Big concessions have been given to large colonizing companies for the economic development of large tracts of country. Of 40 concessionary companies only very few have proved successful. The only benefit derived from this system has been that river transport has been organised and the resources of the country have been made known. The great drawback in A.E.F. is lack of transport. The rivers provide practically the only means of communication, and the execution of the plan of railway construction is urgently desirable. A bill authorizing a loan of 171,000,000 francs for the construction and improvement of all methods of communication was approved in 1920.

*Products.*—Natural produce is varied. Rubber is the chief vegetable resource. It has so far been found impossible to establish practical rubber plantations, and the rubber output of the colony is wild. Rubber exports, naturally, suffered from the world crisis. Exports in 1913 were 1,600 tons, 1914 600 tons, 1915 1,400 tons, 1917 3,000 tons, 1920 2,140 tons worth 14,156,000 francs. The quality is undeniably good, but there is no great demand for this type of rubber on the French market.

The oil palm is the next important resource. It is very widely distributed but was but little exploited before the war. The export of kernels has been greatly encouraged by the administration and has attracted European firms, thanks to which the export figure for 1920 was nearly 7,000 tons of the value of over 4,000,000 francs. Tobacco and cotton grow wild in the colony. Cocoa and coffee cultivation is on the increase and is attracting attention from European firms. Of all the French colonies A.E.F. is the most richly wooded, 54,000 sq. m. being covered by dense forest, in which the presence of mahogany and rosewood, of tulip and walnut, show the diversity of this almost inexhaustible source of wealth. Before long the annual log production will amount to 450,000 tons. In 1921 the figure was 150,000 tons. Exports in 1920 amounted to 66,000 tons of a value of 6,238,000 francs. The possibility of producing wood-pulp on a large scale has to be borne in mind.

So many elephants have been killed that there are large stocks of ivory in the country. Exports of ivory in 1920 amounted to 93,636 kgm., worth 4,700,000 francs.

The export of whale-oil has been recently started. There are large herds of sheep and cattle in the brush country of the northern districts, which will become of increasing value as it is opened up.

There would seem to be a mining future before the country. But few companies have been floated and the underground wealth is still but little known. Copper exists with a yield of 45%, and mines are in some places already being worked, but in a rudimentary fashion, on a belt of about 60 m. in the middle Congo. Railways alone can bring about the proper development of this district, which is 190 m. from the coast.

*General Trade* reached its top pre-war figure in 1913 with 57,846,000 francs. It fell to just over 22,000,000 francs in 1915 and has since slowly picked up. In 1920 the total was 49,801,000 francs, a figure partly due to inflated prices. There are signs, however, of a return to the normal progress in trade. Imports accounted for over 18,000,000 francs of this sum. (G. A.; M. R.*)

**FRENCH LITERATURE** (1910–21).—The period just preceding the World War was one of considerable activity in French literature. Never had thought taken on more varied aspects. Romanticism, classicism, naturalism were all living and thriving side by side with other theories, not to speak of aberrations and follies. A literary critic had counted no fewer than 55 literary "schools," groups or coteries, chiefly made up of young writers, but including not a few who had already won their laurels. Indeed, the tendency had for some time been the breaking-up into groups, each with its particular dogmas and formulas. There was a profusion of ideas; there were even a little confusion and anarchy. The dominant note was a youthful optimism. Men of genius were discovered on all sides; a new and great era was supposed to be opening up for France, which had successfully weathered some tremendous storms and had again taken her place amongst the leading nations of the world. Never had so many people been writing, and never had literary form been

so widely discussed; rarely, too, had the average literary man cut so prominent a figure in the public eye or had his theories so widely proclaimed and discussed. They were to point out the way to new destinies. There had been a great regeneration of nationalism (a "renaissance of French pride," as one writer put it), while a religious revival was also in the air, and side by side with these facts a hundred more or less significant "isms" and scores of leading and general ideas battled in the intellectual arena. French authors mostly develop in harmony with the thought of their times in a manner not usual with Anglo-Saxon writers. The renewed interest in English literature, which has been a notable feature of post-war letters, had also already begun, but the authors now claiming attention are of another school.

The period 1910–20 was marked by a burst of very varied talent and the more or less complete disappearance of literary schools. The most significant of all the new movements was the nationalist one—the love of the land and of the dead, the cult of energy and heroism. At the head of this was Maurice Barrès (b. 1864), whose influence on youth before the World War had its sequel in the great rôle he played during the struggle. Through his individualism and his *nostalgie*, Barrès is the heir of the great Romantics, though a disciplined Romantic; in the preponderance of thought over imagination which we meet with in him, in the purity and nobility of his prose, he is attached to the purest classical traditions. A spectator of all the political turmoils, from the Panama scandals and the Dreyfus case to the World War, which have shaken France and the French, Barrès in a series of interesting works of high quality did his best to interpret and explain them for his contemporaries, and this he continued in his *L'Âme Française pendant la Guerre* and subsequently in *La Génie du Rhin*, in which, with a tumultuous enthusiasm reminiscent of Michelet, he celebrates the great river which is not the river of any one country. It was a great completion of Barrès's work during the war, beginning with *Colette Baudoche*.

New members of the French Academy include M. Joseph Bédier (b. 1864), the historian and critic of the origins of French literature, whose romances, founded on certain of the old sagas, such as *Le Roman de Tristan et Iseult* and *Perceval, ou le Saint-Graal*, contain some of the finest writing produced of late in France. During the war he was at the front as historian, one of the results being his work *L'Effort Français*. René Boylesve (b. 1867), the *mondain* novelist, has been called a writer of pretty stories—stories which he loves to tell and tells charmingly. He has two styles—the novel of provincial life, in which he is a sort of "little Flaubert," and his sentimental and psychological novels, which are not devoid of licentiousness. He likes to imagine love-nests and 18th-century parks, with labyrinths and statues, as settings to gallantry. On the other hand, he has a great respect for tradition, and he orders and organizes the movement of his novels, keeping affairs of the heart and affairs of the mind rigorously apart. The reticence of his novels of provincial life make up in a way for the libertinage of the others. Henry Bordeaux (b. 1870), another new Academician, who published a number of war books (*Le Fort de Vaux*, *La Bataille devant Souville*, appreciations of the lives of young heroes, such as Guynemer, the aviator, etc.), is in his novels a painter of the torments of the heart, who has given a distinguished place in literature to Savoy. In his *Pays Natal* he proclaims his wish to restore to the French provinces the original beauty and intellectual vigour which they have lost, and to restore also the spirit of the family, for "a man only preserves his terrestrial existence and greatness through his origin and his hopes." *La Peur de Vivre* shows the beauty of action, of life accepted with all its duties and responsibilities—the nobility of sorrow and the beauty of sacrifice.

If the new men in the Academy—as out of it—were mostly highly prolific, the "old hands" were comparatively silent. Only some small volumes issued from the pen of the veteran Anatole France (*see* 10.775), who, disgusted with the German intellectuals' espousal of the causes of the war, in spite of his age offered himself as a volunteer to the Government "to carry a gun." In one of these, *Le Petit Pierre*, he goes back again to reminiscences of his boyhood. Paul Bourget (*see* 4.331) published *Le Sens de la Mort*, besides *Anomalies*, a volume of short stories of scientific or psychopathological bent, and *Ecuyère*, a dramatic story, in his early manner, though it differs from much of Bourget's work in showing an aristocrat with an ignoble soul in contrast to others of humbler birth.

It was Paul Bourget who made the notable declaration that during war-time the writer should stick to his writing—that he would accomplish more good in so doing than if, in some burst of enthusiasm, he changed from thought to activity. This, in effect, was the reply made to Anatole France by the French Government. Indeed, the *littérateur* played an important part in France during the war, not only in keeping up the *moral* of combatants and civilians, but in proposing ideas, offering counsel, suggesting projects. The writer's imagination often came to the aid of the soldier's science. Paul Adam (b. 1852) was prolific in suggestions to the high army authorities, and was, long before the fact, responsible for putting forward ideas that were subsequently adopted. Men like Maurice Donnay, Richepin (b. 1849), Barrès busied themselves in keeping the civil population hopeful and consoled. Numbers of these writers were at the head of "war works," and Maurice Donnay (*see* 8.417), the author of *Lysistrata* and *Éducation de Prince*, besides producing a number of works of more or less fugitive interest, in a delightfully humorous one-act comedy showed how the needy "poilus," before returning to the front after their "permissions," were provided by society ladies with socks and shirts and "spoiled" by elderly gentlemen with pipes and pipe-lighters.

Marcel Prévost (*see* 22.312) turned from graceful writing on femininity to more serious (or at any rate more topical) subjects —*Mon cher Tommy* and *La Nuit Finira*. M. Prévost founded after the war a new literary review on the style of *La Revue de Paris*, called *La Revue de France*. Edmond Rostand (*see* 23.754), whose death occurred in 1918, published *Le Vol de la Marseillaise* during the war; *La Dernière Nuit de Don Juan*, in which the brilliant versification met with in *Cyrano* and *Chantecler* is unimpaired, though, as in those works, somewhat disfigured by *calembours* and tricks of phraseology, was published posthumously. One distinguished writer laid down his pen entirely all through the war to take up more active work—Eugène Brieux, who devoted great organizing ability to the care of the blind.

The Academy, as a direct consequence of the war, opened its doors to a number of men not purely or not even at all devoted to the cult of letters. Georges Clemenceau had been indeed the author of a number of works of fiction—*Le Grand Pan*, *La Voile de Bonheur*, etc.; Marshal Foch was known as a good military writer; and from Marshal Lyautey, the governor-general of Morocco, came a valuable work on Morocco, published about the same time as his election.

Among the older men outside the Academy, Henri Duvernois, the author of *Gisèle*, a very fine *conteur*, kept up the tradition of the Maupassant school; and Abel Hermant (b. 1862) joined to the classical purity and elegance of his French a gift of humour, satire and irony, in his novels and his *chroniques* of Parisian life.

Claude Farrère (b. 1876), like Pierre Loti (b. 1850), a naval officer and also a Turcophil, had, unlike the Academician, embraced the Mussulman faith, yet in spite of this in his novels he is particularly interested in modernism and the cosmopolitan society of oriental capitals. His work is of the most varied character, and the period under review saw from his pen *Bêtes et Gens qui s'aimèrent*, *La Dernière Déesse* and *Les Condamnés à Mort*, a novel of "anticipation" *à la* H. G. Wells.

The death of Paul Adam (*see* 1.172) in 1920 removed one of the most remarkable, supple and prolific of French writers. At first a violent impressionist and naturalist, he became in turns mystic and sociologist, and set himself especially to writing novels founded on the ideas of the time. His work is so copious that it has been said to resemble overgrown vegetation; Remy de Gourmont described him as a "magnificent spectacle." The thought is fatigued in trying to follow him, and his style is crabbed and often incorrect. But as a whole his work gives an impression of immense power, his metaphors convey great and

the abortive operations near Festubert embarked on a few days later; and the important victory won in Sept. in the region of Loos. During the seventeen months that the field-marshal led the British troops in the field, these rose, excluding cavalry, from an original total of five divisions at the front to a total of 34 divisions; these he had organized as three armies. His forces up till the last three months suffered greatly from a lack of artillery ammunition, except during the opening weeks of the campaign; this hampered his operations to an extent not experienced by his successor. He resigned in Dec., Sir D. Haig taking his place, and he returned to England, to be raised to the peerage as Viscount French of Ypres and High Lake in recognition of his great services. He then became commander-in-chief in the United Kingdom, and he held that appointment until May 1918, when he was selected to be Lord-Lieutenant of Ireland. This position he occupied under most trying conditions until early in 1921, the political state of the country growing worse and worse. On resigning he was rewarded with an earldom.

At the end of the war, Lord French published his personal narrative under the title, "*1914*."

**FRENCH EQUATORIAL AFRICA** (*Afrique Equatoriale Française;* or *A.E.F.*), formerly FRENCH CONGO (*see* 11.99), is an immense region stretching from the mouth of the Congo to Tripoli, from the Atlantic to Egypt, covering an area of about 870,000 sq. miles. It is therefore more than four times the size of France. The coast is but little developed and is as a rule flat and sandy. There are few good ports. At a short distance from the Atlantic the country rises to a plateau between 2,300 and 2,700 ft. high, in which lies the vast depression of the closed basin of the Chad. The chief characteristic of the colony is its magnificent river system. It has the Congo for a distance of 370 m. of its course of 2,500 m., its great tributaries (the Sanga or Sangha and Ubangi), the Ogowe (801 m.), and the huge expanse of Lake Chad, which receives the water of the whole of the Schari and Logone valleys. In natural characteristics there are two clearly distinct zones—forest and brush. Tropical forest with luxuriant vegetation and intense animal life covers the Gabun and the valleys of the Sanga and Ubangi; brush reigns up to and beyond Lake Chad. The climate is extremely humid and painfully hot.

Estimates of the population range from 6 to 10 millions. Sleeping sickness is very prevalent. There are many different races and varied types among the natives, but two main groups can be recognized. There are the sedentary people of the forest zone who are very savage and occasionally cannibal, but can adapt themselves to agriculture, and the Nomad tribes of the brush country who are warlike herdsmen influenced by Islam.

A.E.F. is a colony of special growth. Its frontiers were laid down by diplomacy before the country had been explored. The main steps in French occupation of Equatorial Africa were:—(I.) Foundation of French Congo (1842–82), and the great exploration expeditions of de Brazza. (II.) The Berlin Conference and the General Act of 1889 which established international understanding with regard to freedom of navigation and trade in basins and mouths of the Congo and the Niger, and as to the formalities to be observed in order to make the fresh occupations of Africa effective. (III.) The period of political and diplomatic action over the Congo between 1889 and 1909, when a number of Boundary Conventions were signed. (IV.) French expansion towards the Upper Nile, which gave rise to the Fashoda incident (1898) and a declaration in 1899 in which the eastern limits of the French zone of influence in West Africa were laid down. (V.) French expansion in the Chad. The work of the great explorers Crampel, Maistre, Gentil and Maj. Lamy brought about the realization of the ambitious plan of linking up, through Lake Chad, the oases of Algeria and the shores of the Ubangi.

In 1911, following upon the Agadir incident, A.E.F. enabled France to compensate Germany for the rights she ceded to France in Morocco. The colony then lost nearly 100,000 sq. m. of territory, which was joined on to German Cameroon. This was restored by the Treaty of Versailles.

*Administration.*—A.E.F. is an amalgamation of four different colonies under a governor-general. This post was created by decree June 26 1908, and a further decree Jan. 15 1910 gave definite form to the new administration.

The Government General of French Equatorial Africa consists of the following colonies:—

Gabun (cap. Libreville) 104,000 sq. m. Middle Congo (cap. Brazzaville) 89,000 sq. m. Ubangi-Schari (cap. Bangi) 193,000 sq. m. Chad (March 17 1920) 482,000 sq. m.

The supreme administrative head is the governor-general who resides at Brazzaville. The different colonies preserve their administrative and financial autonomy and are governed by lieutenant-governors with the exception of the Chad, which has either a civil or a military administrator. A government council assists the governor-general, who has his delegates in Paris at the Office Colonial and at the Supreme Colonial Council.

*Colonisation.*—The policy pursued with regard to colonization of this vast country has not been very successful. Big concessions have been given to large colonizing companies for the economic development of large tracts of country. Of 40 concessionary companies only very few have proved successful. The only benefit derived from this system has been that river transport has been organised and the resources of the country have been made known. The great drawback in A.E.F. is lack of transport. The rivers provide practically the only means of communication, and the execution of the plan of railway construction is urgently desirable. A bill authorizing a loan of 171,000,000 francs for the construction and improvement of all methods of communication was approved in 1920.

*Products.*—Natural produce is varied. Rubber is the chief vegetable resource. It has so far been found impossible to establish practical rubber plantations, and the rubber output of the colony is wild. Rubber exports, naturally, suffered from the world crisis. Exports in 1913 were 1,600 tons, 1914 600 tons, 1915 1,400 tons, 1917 3,000 tons, 1920 2,140 tons worth 14,156,000 francs. The quality is undeniably good, but there is no great demand for this type of rubber on the French market.

The oil palm is the next important resource. It is very widely distributed but was but little exploited before the war. The export of kernels has been greatly encouraged by the administration and has attracted European firms, thanks to which the export figure for 1920 was nearly 7,000 tons of the value of over 4,000,000 francs. Tobacco and cotton grow wild in the colony. Cocoa and coffee cultivation is on the increase and is attracting attention from European firms. Of all the French colonies A.E.F. is the most richly wooded, 54,000 sq. m. being covered by dense forest, in which the presence of mahogany and rosewood, of tulip and walnut, show the diversity of this almost inexhaustible source of wealth. Before long the annual log production will amount to 450,000 tons. In 1921 the figure was 150,000 tons. Exports in 1920 amounted to 66,000 tons of a value of 6,238,000 francs. The possibility of producing wood-pulp on a large scale has to be borne in mind.

So many elephants have been killed that there are large stocks of ivory in the country. Exports of ivory in 1920 amounted to 93,636 kgm., worth 4,700,000 francs.

The export of whale-oil has been recently started. There are large herds of sheep and cattle in the brush country of the northern districts, which will become of increasing value as it is opened up.

There would seem to be a mining future before the country. But few companies have been floated and the underground wealth is still but little known. Copper exists with a yield of 45%, and mines are in some places already being worked, but in a rudimentary fashion, on a belt of about 60 m. in the middle Congo. Railways alone can bring about the proper development of this district, which is 190 m. from the coast.

*General Trade* reached its top pre-war figure in 1913 with 57,846,000 francs. It fell to just over 22,000,000 francs in 1915 and has since slowly picked up. In 1920 the total was 49,801,000 francs, a figure partly due to inflated prices. There are signs, however, of a return to the normal progress in trade. Imports accounted for over 18,000,000 francs of this sum. (G. A.; M. R.*)

**FRENCH LITERATURE** (1910–21).—The period just preceding the World War was one of considerable activity in French literature. Never had thought taken on more varied aspects. Romanticism, classicism, naturalism were all living and thriving side by side with other theories, not to speak of aberrations and follies. A literary critic had counted no fewer than 55 literary "schools," groups or coteries, chiefly made up of young writers, but including not a few who had already won their laurels. Indeed, the tendency had for some time been the breaking-up into groups, each with its particular dogmas and formulas. There was a profusion of ideas; there were even a little confusion and anarchy. The dominant note was a youthful optimism. Men of genius were discovered on all sides; a new and great era was supposed to be opening up for France, which had successfully weathered some tremendous storms and had again taken her place amongst the leading nations of the world. Never had so many people been writing, and never had literary form been

dun, who had written some striking novels of "anticipation" on the forms of future warfare; the brothers Ernest and Michel Psichari; Charles Müller, a brilliant critic and romanticist; André Lafon, poet and novelist, who had gained the Grand Prix for literature of the French Academy; André du Fresnois, poet, novelist and critic; Lucien Bonneff, the author of popular works on the theories of socialism; Émile Nolly, a writer of novels on colonial life (chiefly of Annam); Charles d'Olonne, an explorer besides being a man of letters; Claude Casimir-Périer, son of a former president of the republic, the author of works on the mercantile marine and maritime questions. A number of remarkable poets also disappeared in the great struggle, among them Pierre Fons, a "laureate" of the Academy, Robert d'Humières, Guillaume Apollinaire, Lionel des Rieux.

The best remembered of all those who fell before the enemy is Charles Peguy, who died an heroic death in the first few months of the war. The poet of *Jeanne d'Arc*, and Grand Prix of the Academy, he was a leader in the school of Barrès and a disciple of the fervent nationalism which had such an extraordinary effect on the young men of France. The founder and director of the famous *Cahiers de la Quinzaine*, which saw the birth of numbers of remarkable works, he came of peasant stock and joined to a profound love of democracy a sort of national-religious mysticism (like the Christian socialist patriotism of the men of 1848). He dedicated his *Jeanne d'Arc* "To all those who have learned the remedy (to the universal evil); to all those who have lived their human life; to all those who have died from their moral life for the establishment of the Universal Socialist Republic." Later works of his were *L'Appel aux Armes*, *Le Voyage du Centurion*, etc.

Léon Daudet's (b. 1868) name (he is also of the "Goncourts") is one of those most on people's lips, and naturally so when we remember his tremendous production on political, national and other subjects during the war (to say nothing of his polemical writings as editor of the *Action Française*, and his vigorous trenchant style. Up to 1921 his latest incursion into pure literature was entitled *L'Amour est un Songe*. But Léon Daudet is one of the most picturesque figures of modern France, and his *Memoirs* will be a valuable addition to the history of the epoch.

Several notable women writers had in 1921 recently passed away, the most picturesque among them perhaps being Judith Gautier (1850–1919), the gifted daughter of a man of genius and the one-time wife of another, Catulle Mendès. Most of her novels and stories had their scenes laid in China or Japan, being reminiscences of the teaching of her former professor, the Chinaman whom her father found wandering in the streets of Paris and took home with him. Madame Daniel-Lesueur (1850–1921), starting as a poet with great talent and the translator of Byron, wrote a larger number of novels showing great powers of observation and vivacity, though in her latter years she had risen little above the feuilleton type.

Among the names of prominent women writers may be cited the Comtesse de Noailles, who was awarded the French Academy prize for literature (10,000 francs) in 1921, Marcelle Tinayre (b. 1872), Colette Yver (b. 1874), Jeanne Landre, Lucie Delarue-Mardrus (b. 1880), Marie-Anne de Bovet. "Colette" followed up her success in *Vagabonde* with *Chéri*, which depicts exactly the same sort of society and with an equally remarkable talent, and another work showing her exceptional love and understanding of animals. Marguérite Audoux, the seamstress authoress of *Marie-Claire*, subsequently followed this work up with a sequel called *L'Atelier de Marie-Claire*, though the second work cannot be said to possess the same qualities as the one which led Octave Mirbeau to find a publisher for her. In general it may be said of French women writers, as of those of other countries, that their treatment of many subjects is bolder and more outspoken than that of the men.

Two women writers notably have got their inspiration from the East, where both of them were born—Miriam Harry, a gifted writer, the child of French parents settled in Palestine, and Elissa Rhais (authoress of *Saada la Marocaine* and *Le Café-Chantant*), a Mohammedan lady from Algeria, whose mother, she tells us, used to relate to her interminable stories in the manner of the *Arabian Nights*.

A feature of French literature worth noting is the long list of "regionalist" writers, who lay the scenes of their romances in and depict the life of particular parts of the provinces with which they are most familiar. Thus we find Henry Bordeaux devoting himself especially to the Dauphiné, while Paul Bourget is the special mouthpiece of the Auvergne, as Maurice Barrès is of Lorraine. J.-H. Rosny *jeune* (*see* 23.739) places a good many of his scenes in the Landes, while there are several novelists who devote themselves to Provence, including Edmond Jaloux and E. Henriot. Writers on the Basque country include Pierre Loti, Paul Faure (b. 1876) and others. Madame Lucie Delarue-Mardrus is the writer for Normandy, Marc Elder and André Savignon (who gained the Prix Goncourt for his *Filles de la Pluie*) for the Ocean (Ushant and the Isles). Pierre Guitet-Vauquelin (b. 1882) is the special writer for the Central Pyrenees and Corsica, and there are others who make a specialty of the Bas-Languedoc, Anjou, Brittany, etc. Indo-China finds interpreters in Pierre Mille (b. 1864), Loti, Farrère, while the list of romanticists for Algeria, Morocco and French Africa is a long one.

Among the poets of 1921 a leading place was taken by Fernand Divoire (b. 1883), the symbolist, who had since the war published a volume entitled *Ames*, with a decided Shakespearean inspiration. Divoire is a champion of the most advanced schools, including "cubism"; he is also particularly interested in the technique and art of the dance, and has written on the art of Isadora Duncan. Henry Bataille (b. 1872), the prolific and popular dramatist, published *La Divine Tragédie* and other poems during the war. Paul Valery is a poet who enjoys a remarkable reputation abroad. Paul Fort (b. 1870), the so-called "Prince of Poets," author of a seemingly interminable series of *Ballades Françaises*, continued to produce his remarkable personal, Puck-like, capricious and prolific muse. Some of his admirers have compared him to Walt Whitman. There is truly something of Whitman in him, but it is perhaps more true to say of him that when he is least like himself he is imitating Paul Fort. "I make all lyres vibrate," he says. "The human soul is my religion. I am a poet—solely a poet. In other words, a dreamer, a conscious creator. Or again, and above all, a creating God, a dreaming God." *Spirituel*, picturesque, solemn or comic, he has always a wonderful command of phraseology and of the *vers libre*, and above all, he is essentially French. "Paul Fort is a mask," one writer says of him, "and under that mask is the familiar daemon of the land of France." Jules Romain, of the group or "chapel" of the *Nouvelle Revue Française*, and founder of the style of "Unanisme," or the absolute expression of reality in verse, has produced *Le Voyage des Amants* in *vers libre*. Maurice Magre (b. 1877), author of *La Montée aux Enfers*, who is also a dramatist, began his career as a poet of social inspiration, but turned Baudelairian. Francis Carco, the humorist, is a poet of a very sensitive muse.

French criticism suffered severely in the loss of the two veteran critics Jules Lemaître (*see* 16.408) and Émile Faguet (*see* 10.125). Jules Lemaître (1853–1914) was the man of an epoch, and he disappeared when that epoch finished. Poet, dramatist, novelist and critic, he rendered the most service in this last capacity. An admirer and disciple of Flaubert, he was imbued with the particular modernism and fantasy of that master. In the little notebooks he filled at the time with all sorts of impressions, bold, brilliant and often tumultuous, is found the nucleus of all his afterwork. His volumes of criticisms on his "Contemporaries," who included the Parnassians and the Symbolists, and all the leading figures of the middle of the last century, are particularly valuable. A keen analyst, ironical, sceptical and ingenious, mingling the finesse of a metaphysical moralist with the fantasy of a dilettante, and unable to accept the finality of any judgments ("One must not worry too much about the future," was one of his sayings), his work is marked by an intense personality and by novel opinions on old subjects. The inventor of the impressionistic method of criticism, if he severely flagellated some of his contemporaries, he succeeded in making criticism a living and enduring thing. Émile Faguet (1847–1919), by the variety of his encyclopaedic knowledge and his independent views (sometimes over-independent), had in his latter years, without abandoning the study of letters, devoted himself more especially to the study of contemporary sociology in its various forms. Thus among his last works were two volumes on *Le Culte de l'Incompétence* and a continuation *Et l'Horreur de la Responsabilité*. Criticism was in 1921 represented by Paul Souday, the well-known literary critic of the *Temps*, Fernand Vandérem (b. 1864), Adolphe Brisson (b. 1860), editor of *Les Annales Politiques*, René Doumic (*see* 8.450), of the French Academy, and Camille Mauclair (b. 1872).

History is chiefly represented by Gabriel Hanotaux (*see* 12.923), the author of a voluminous *History of France*, Ernest Lavisse (*see* 16.294), Aulard (*see* 2.916) and Lenôtre (b. 1857), the author of brilliant works on 18th-century characters and the Napoleonic era.

The drama had a serious setback in France during the war, when old favourites for the amusement of the "*permissionaires*" had it all their own way. The most prolific and most popular dramatist in 1921 was Henry Bataille, who, though several of his pieces have been slightly suggested by the war, has given it as his opinion that the war can have and should have no durable effect on art. Within a short couple of years several of his highly literary pieces had been produced—notably, *Tendresse*, *Les Sœurs d'Amour*, and *L'Homme à la Rose*. Sacha Guitry (b. 1885), a phenomenon in himself, has latterly been represented by his studies of those two great Frenchmen, *Béranger* and *Pasteur*, and by his lighter pieces, *Je t'aime*, *Le Comédien*, and *Le Grand Duc*. Among other notable playwrights who have been particularly prominent may be mentioned De Curel (*see* 7.637), with his "*pièces à thèse*" (*L'Âme en Folie*, etc.), Maurice Magre (*La Mort Enchaînée*, *Arlequin*, a fairy comedy), Carco, the versatile humorist with his study of apaches and low life generally (*Mon Homme*), Lucien Descaves (b. 1861), *L'As du Cœur*, one of the best of a series of post-war plays dealing with the problem of the returned combatant, Lenormand, André le Lorde (b. 1871) (of the Grand Guignol), Zamacois, Fauchois (*Baethoven*, etc.), St. Georges de Bouhelier, Bernstein (b. 1876), M. Hennequin, and that indefatigable writer of farces, Henry de Gorsse (b. 1868), who had several thousand pieces, written, alone or in collaboration, to his credit.

It must be added that great influence had of late been exerted on the drama and letters by the Théâtre du Vieux-Colombier, which, under the direction of J. Copeau, had become a veritable nursing home of ideas and was *par excellence* the leading classical international theatre.

(S. S.)

**FRENCH WEST AFRICA** (*l'Afrique Occidentale Française*, or *A.O.F.*; *see* 11.205).—By 1921 France had formed out of all her West African possessions an administrative whole constituting a vast country six times larger than France, and its riches were being continuously developed. The settlements thus linked together are separated one from another on the Atlantic seaboard by intervening foreign possessions but become merged in the depth of the continent. They cover an area stretching south of Morocco and Algeria to the Chad and Congo of nearly 1¼ million sq. m., with a pop. of about 11 millions. The colonies thus grouped are:—

Senegal (cap. St. Louis) 76,000 sq. m., pop. 1,250,000. Upper Senegal-Niger (cap. Woulouba) and Upper Volta (cap. Ouaga Dougou) together 315,000 sq. m., pop. 5,645,000.

Guinea (cap. Konakry) 107,000 sq. m., pop. 1,809,000. Ivory Coast (cap. Bingerville) 83,000 sq. m., pop. 1,300,000.

Dahomey (cap. Porto Novo) 41,300 sq. m., pop. 225,000. Mauretania, between the Rio de Oro and Senegal, 100,000 sq. m., pop. 225,000.

Niger Territory (cap. Zinder) 714,000 sq. m., pop. 225,000.

Along the whole coast south of the Rio de Oro to the bend of the Niger there is only one port worthy of the name, Dakar, which has modern equipment. With the exception of Dakar and Konakry on the Guinea coast there are only river ports such as St. Louis on the Senegal. Two vast rivers flow through French West Africa; they have annual floods but are not everywhere navigable and their mouths are obstructed by cataracts and barrages. They are the Senegal (1,060 m.) and the Niger (over 2,500 m.), the latter of which forms an immense curve up to Timbuktu. On the Ivory Coast and in Dahomey lagoons run parallel with and a short distance from the sea. They are navigable by specially constructed boats. The physical configuration of the country has made its penetration arduous. The Saharan desert on the north, dense equatorial forests on the south and an unfriendly sea-coast for long shut out the explorers. Climate changes according to the distance from the coast. In the south rains are heavy and steady. The natives represent many different branches of the black race, Sudanese, Mandingoes, Bambaras, Ouslops and Ashanti. A governor-general, residing at Dakar, is at the head of the administration, and the colonies under him, which preserve their administrative and financial autonomy, are governed by lieutenant-governors.

The railways (1,860 m.) are being greatly developed. Existing lines in 1921 were Dakar, St. Louis, Thies–Kayes, Kayes–Niger.

Oil products, textile and fibre are the chief exports. Nuts are the great resource of Senegal. The total oil exports of 1919 amounted to 230,260 tons, of which nuts formed the bulk. They are shipped shelled and unshelled. Shelling economizes about 50% in freight. Oil made from these ground-nuts has conquered the market. Cakes made with this oil are being increasingly used in the feeding of cattle. The oil palm which is found in Guinea, and especially in the Lower Ivory Coast and Dahomey, is very productive. The covering of the palm-nut yielded 36,000 tons, of which 35,000 tons were exported in 1919. The kernel oil produced in 1919 amounted to 102,000 tons, of which 98,538 tons were exported.

The production of textile and fibrous material is not great, but there are considerable possibilities. The natives have always grown cotton, and successful attempts to grow cotton industrially have been made in Senegal, Upper Senegal, the Niger, Ivory Coast and Dahomey. In the Sudan and Senegal irrigation is necessary, and according to experts the valley of the Niger is as good as that of the Nile in this respect. A great irrigation scheme was being prepared in 1921. Timber resources are vast. The forest of the Ivory Coast, which covers two-thirds of the colony, measures 70,000 square miles. Mahogany exports in 1919 were 35,000 tons. Proper working of the forest will give vast quantities of wood, 30% of which is suitable for furniture. The general trade amounted in 1919 to 630,260,000 fr. (300,433,000 imports), showing a considerable falling off from the 1918 figures, which were 853,060,000 fr. (575,271,000 imports). There were signs, however, that in 1920 there would be a great improvement.

**FRENCH WEST INDIES.**—Martinique and Guadeloupe (*see* 17.801 and 12.645), belonging to France, form one of the small West Indian colonies in the Atlantic Ocean.

*Martinique.*—The total pop. was 193,087 inhabitants who, with the exception of the immigrants, are all classed under the general denomination of Creoles. Fort de France, the capital of the colony, has 27,000 inhabitants, and is the only large place in the island since the destruction of St. Pierre in 1902. The produce of Martinique consists principally of sugar-cane and its derivatives. The trade of the colony in 1919 amounted to 247,375,000 fr., of which 74,670,000 were imports and 172,705,000 were exports. The trade figures for 1918 were 105 million fr., this being 25 million fr. more than the average for the five years 1913–7. As in the case of Guadeloupe, France and her colonies account for only about one-third of the imports, while they absorb about nine-tenths of the exports.

*Guadeloupe.*—The pop. of Guadeloupe and the outlying islands is 190,503. About nine-tenths consists of Creoles; it comprises whites, half-breeds and blacks, between whom there is considerable friction. Guadeloupe has two large towns: Pointe-à-Pitre, a busy place (22,664 inhabitants), and Basse-Terre, the capital (8,184 inhabitants). The trade of Guadeloupe and its dependencies in 1919 amounted to 90,766,879 fr., of which 39,696,000 fr. were imports and 51,070,824 were exports. This total represents an increase of 33,500,000 fr. on the average for the five years 1913–7. About one-fourth of the imports came from France, while almost the whole of the exports went to the mother-country.

**FRENSSEN, GUSTAV** (1863– ), German author, was born at Barlt Oct. 19 1863, and was educated at the universities of Tübingen, Berlin and Kiel. He took orders and from 1892 to 1902 was pastor at Hemme, taking his degree as doctor of theology at Heidelberg in 1903. But he had already for some years been known as a writer of novels, and in 1902, a year after his great success with *Jörn Uhl* (1901), he gave up his pastorate and devoted all his time to literature. His work in fiction includes *Die Sandgrafin* (1895, 3rd ed. 1902); *Die drei Getreuen* (1898); *Hilligenlei* (1905); *Peter Moor's Fahrt nach Süd-West* (1906); *Klaus Henrich Baas* (1909) and *Die Brüder* (1918). He also published sermons (*Dorfpredigten*, 1899–1902), and two plays, *Das Heimatsfest* (1903) and *Sönke Erichsen* (1912).

See H. M. Elster, *Gustav Frenssen, sein Leben und sein Schaffen* (1912); also studies by E. Muesebeck (1908) and T. Rehtwisch (1902); and *Gustav Frenssen: Hilligenlei als Kunstwerk und als Tendenzschrift* (1906).

**FREUD, SIGMUND** (1856– ), Austrian physician and psycho-analyst, was born on May 6 1856 at Freiberg in Moravia, and studied medicine and psychology at Vienna, being strongly influenced by Brücke in the latter subject. He took his doctor's degree in 1881, became a member of the teaching faculty in 1885, extraordinary professor in 1902 and ordinary professor in 1919. After working in Paris under Charcot in 1885–6, he devoted himself, under his influence and in coöperation with the Viennese physician, Josef Breuer, to the study of nerve cases. The results of their joint investigations were published in 1895 as *Studien über Hysterie*, of which several editions have appeared, expounding a new treatment, the so-called *catharsis*. This consisted in putting the patient in a hypnotic state, and the examination by the physician, while under this condition, of the forgotten original circumstances under which the symptoms first appeared. Subsequently Freud pursued a path of his own, and developed a special technique, abandoning hypnosis in favour of the so-called "psycho-analytic" method, under which the pathogenic material of which the patient was unconscious was revealed by means of free association and by the interpretation of dreams, etc. The technique and the results of this research work are explained in Freud's most important works: *Die Traumdeutung* (6th ed. 1921), *Psychopathologie des Alltags* (7th ed. 1920), *Drei Abhandlungen zur Sexualtheorie* (4th ed. 1920). Freud's smaller works were collected in four volumes under the title, *Kleinere Beiträge zur Neurosenlehre*. Freud also published two general sketches of his theory: a shorter one, *Fünf Vorlesungen über Psychoanalyse* (delivered at Worcester, Mass., in 1909), and a comprehensive one in *Vorlesungen zur Einführung in die Psychoanalyse*. These medical-psychological studies yielded surprising results in relation to other subjects, and in the possibilities of their adaptation in other branches of knowledge, *e.g.* mythology and the history of religion, civilization and literature. The principal works in this connexion are *Totem und Tabu* (2nd ed. 1920), *Der Witz* (3rd ed. 1921), *Eine Kindheitserinnerung Leonardo da Vinci* (1916), *Jenseits des Lustprinzips* (1920), *Massenpsychologie und Ich-analyse* (1921). Freud's works have been translated into English in collected form. He was given an honorary degree by Clark University, Worcester, Mass.

**FRICK, HENRY CLAY** (1849–1919), American manufacturer and philanthropist, was born at West Overton, Pa., June 19

1849. As a boy he was a clerk for his grandfather who was a distiller and flour merchant; but he early became interested in the coke business. In 1871 he organized the firm of Frick & Co., which ultimately acquired large coal deposits and ran 12,000 coke ovens. He was chairman of the board of Carnegie Bros., from 1889 to 1892, and in the latter year, during the Homestead strike, was shot and stabbed by Alexander Berkman, an anarchist. He was a director of the Pennsylvania, the Santa Fé, and other railways, and of the U.S. Steel Corporation. He died in New York Dec. 2 1919.

To his family and friends he left $25,000,000, estimated at the time to be one-sixth of his estate. To his daughter he left about $6,500,000 to be expended in educational and charitable work. To the city of Pittsburgh he left land for a park (its value being estimated at $500,000), together with endowment of $2,000,000. His New York mansion, with its collection of paintings, bronzes, and enamels, he bequeathed to the city on the death of his wife; and he added an endowment of $15,000,000 for the support of this "Frick Art Collection." He divided his residuary estate into 100 equal parts, each of a tentative value of $500,000. One share was left to many Pennsylvania hospitals and charitable homes, three shares to the Lying-in Hospital (New York), ten shares to the Mercy Hospital (Pittsburgh), ten shares to the Frick Educational Fund, ten shares to the Massachusetts Institute of Technology, ten shares to Harvard University and thirty shares to Princeton University. The value of his New York mansion and its art collection was estimated, in 1920, to be $50,000,000. Among the chief treasures are the Fragonard panels, purchased from the Morgan collection in 1915 for $1,250,000, Bellini's "St. Francis in the Desert" (costing $250,000), Velasquez's "Philip IV." (costing $400,000), Van Dyck's "Paola Adorno" (costing $400,000), Rembrandt's "Portrait of Himself," Gainsborough's "The Mall" (costing $300,000), and the same artist's "The Hon. Anna Duncan" (costing $400,000). Other paintings are fine examples of Titian, Vermeer, Frans Hals, Ruysdael, Cuyp, Rubens, El Greco, Goya, Sir Thomas Lawrence, Millet, Raeburn, Reynolds, Romney and Turner.

**FRIEDRICH, JOHANN** (1836–1917), German theologian (*see* 11.216), died in 1917.

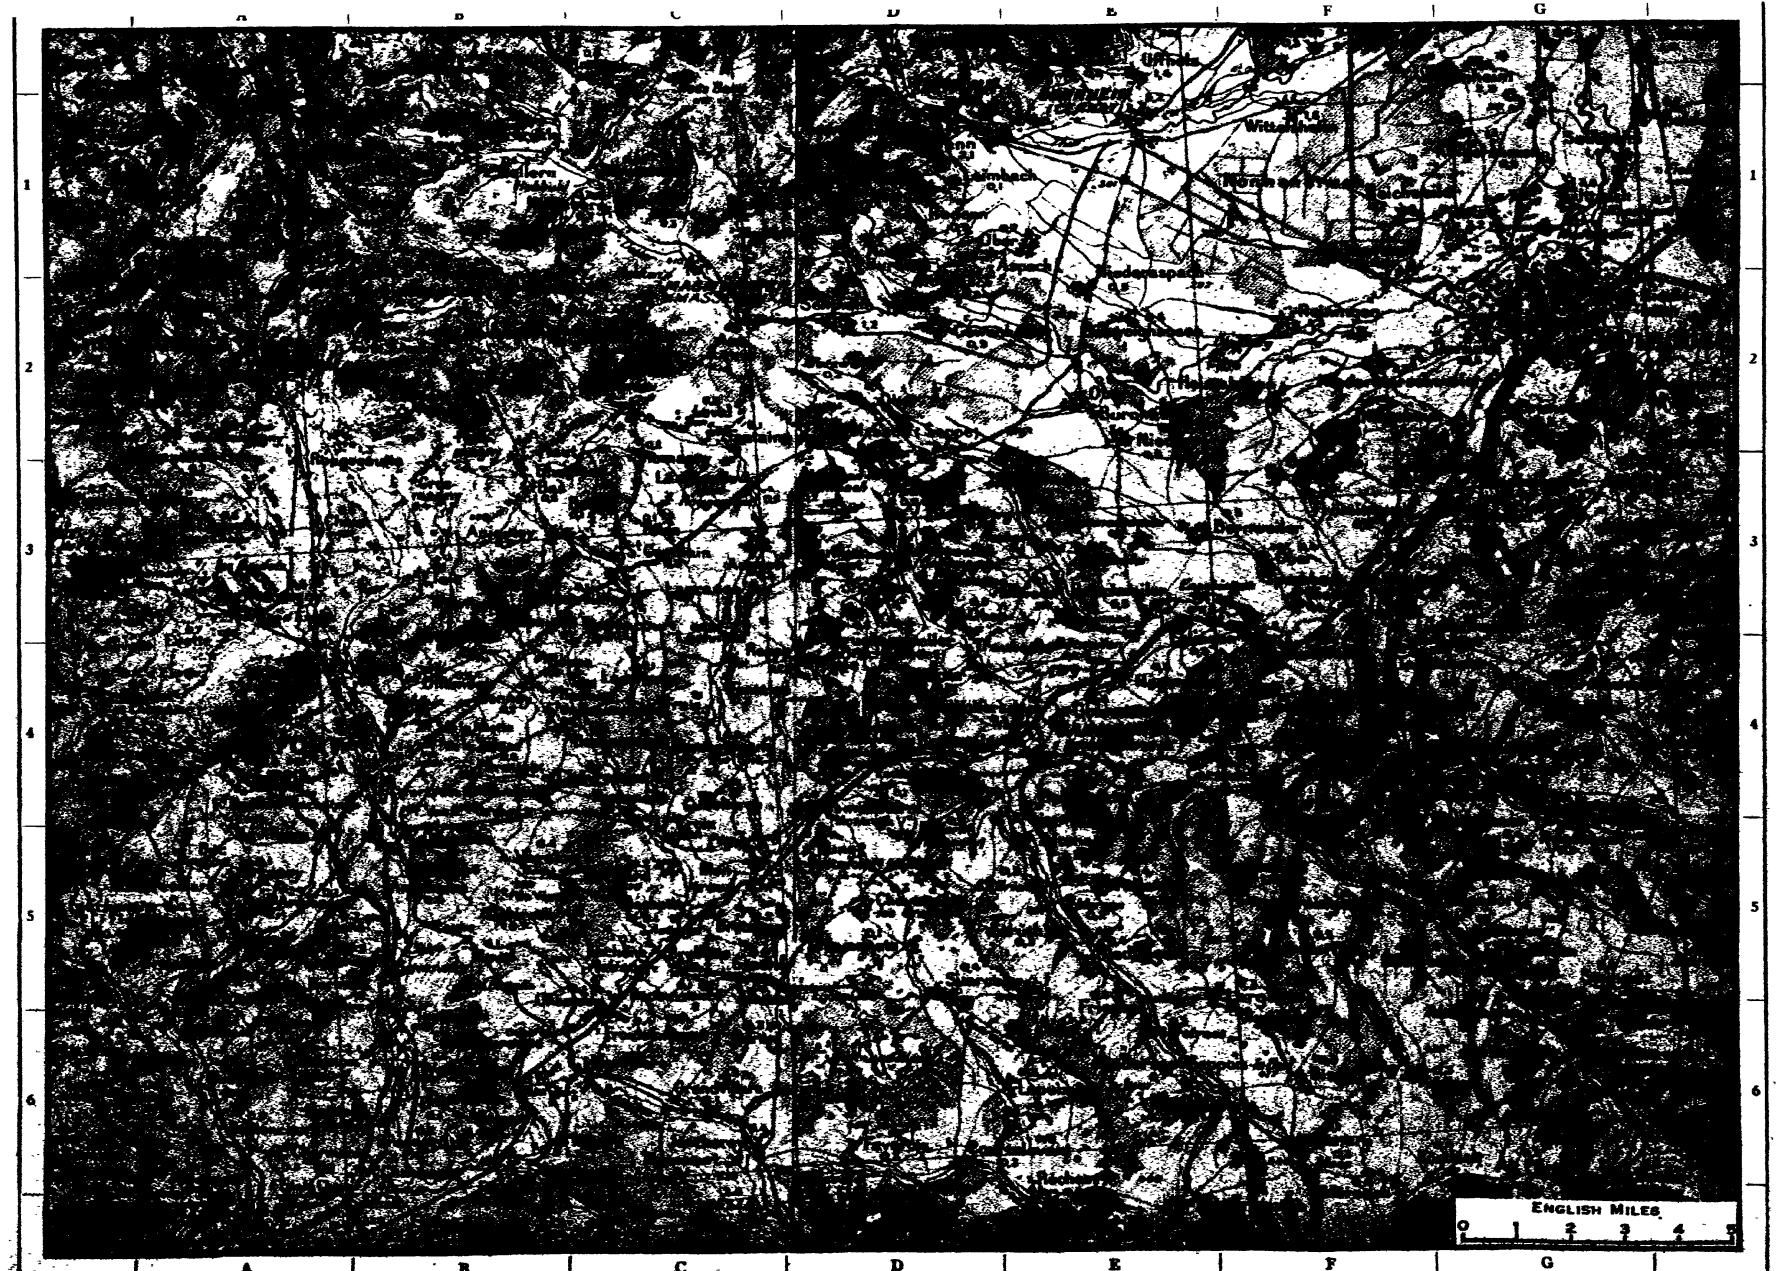
**FROHMAN, CHARLES** (1860–1915), American theatrical manager, was born at Sandusky, O., June 17 1860. At the age of twelve he started to work at night in the office of the *New York Tribune*, attending school by day. In 1874 he began work for the *Daily Graphic* and at night sold tickets at Hooley's theatre, Brooklyn. In 1877 he took charge of the Chicago Comedy Co., with John Dillon as star in *Our Boys*. He next joined William Haverly and his Mastodon Minstrels as manager, touring the United States and Europe. Then for a time he was associated with his brother Daniel in managing the Madison Square theatre, New York. In 1888 he presented Bronson Howard's *Shenandoah* in a revised form, which was a great success. In 1890 he organized the Charles Frohman Stock Co. On Jan. 25 1893 he opened his Empire theatre, New York, with *The Girl I Left Behind Me*, and here he presented many of his stars. Other New York theatres with which he was at various times connected were the Criterion, Garrick, Knickerbocker, Lyceum, and Savoy. He was an adept in developing talent. Among his successful players were Maude Adams, Ethel Barrymore, Blanche Bates, Billie Burke, William Gillette, and Otis Skinner. During 1905–6 he presented E. H. Sothern and Julia Marlowe in Shakespearean plays. Sir James Barrie's plays were favourites with him, and he produced many of Henry Arthur Jones's and Pinero's. He was one of the organizers of the syndicate which for several years controlled the American theatres. Beginning with 1897 he presented many plays in London, leasing at different times such houses as the Duke of York's, Globe, Comedy, Vaudeville and Adelphi. He perished when the "Lusitania" was sunk by a German submarine May 7 1915.

**FRONTIERS, BATTLES OF THE.**—The generic name of "battles of the frontiers" covers the whole of the actions fought at the opening of the World War in Aug. 1914 on or near the French frontiers. They are described separately below.

### (1.) Early Operations in Upper Alsace

*First Entry of the French into Mulhouse.*—In 1914 the Upper Vosges formed a wall between the French Lorraine and the plain of Alsace, taken from France in 1871. On the other hand, to the S. of this wall, the large open gap between the Vosges and the Swiss Jura presented an easy crossing from the Rhine valley into the Mediterranean basin. This gap, a historic gate of the Gauls, was defended on the French side by the fortress of Belfort which gave it its name. A little E. of the fortress the Franco-German frontier separated the area of Belfort from that of Upper Alsace which has Mulhouse as the centre and is commonly called Sundgau.

In the critical days at the end of July 1914, the French Government, wishing to avoid all chance of premature collisions, directed its covering troops to hold themselves at a distance of at least 10 km. back from the frontier, a precaution which served only to deplete of French troops the heights of the Upper Vosges, of which the Germans took possession without firing a shot, and to confine the troops of Belfort within their fortifications while the enemy made repeated incursions into French territory.



Mobilization had only just been ordered when Gen. Bonneau, who was in command of the French troops from Gérardmer to the Swiss frontier, received instructions to take the offensive, and to advance on Mulhouse with the 8th Cavalry Div., the VII. Corps (14th and 41st Divs.) and a brigade of infantry from the garrison of Belfort attached to the 14th Division. The object of this offensive was, it seems, to destroy the Rhine bridges, and to mask Neubrisach; but without doubt the High Command counted much on the political effect that the immediate arrival of the French would produce.

However that may be, the offensive began on the morning of Friday, Aug. 7th, and its start was promising. During the day, on the right Altkirch was captured after hand-to-hand fighting by a brigade of the 14th Div. and a brigade of dragoons; in the centre, the two other brigades of the 14th Div. occupied, after an advance-guard action, the line Aspach-Burnhaupt-Ammertzwiller; on the left, the 41st Div., which had descended the Thur valley, reached Thann and threw out an advance guard towards Cernay.

The next day, while one of its brigades stationed itself at Altkirch, the VII. Corps continued its march forward without resistance. The 41st Div. thus advanced to Lutterbach, and the 14th Div. reached Mulhouse, which it entered at about 6 P.M., with bands playing and flags unfurled, having been preceded by a strong advance guard which pushed beyond the town towards Madenheim and Rixheim.

This unresisted advance was so abnormal that it filled Gen. Curé, commanding the 14th Div. already warned by uncertain rumors, with fears which were soon confirmed by more definite information. The general learned that large German forces had been observed both in the directions of Mülheim and towards Neubrisach, that the Harth Forest swarmed with *Pickelhaubes*, and that the German advance guards had been seen in the Ile Napoleon at a distance of a few kilometres from Mulhouse. Not wishing to run the risk of being caught in a trap, he decided to withdraw his troops from the town, taking advantage of the night to establish them on the heights. The evacuation commenced at 2 A.M., eight hours after the entry into Mulhouse, and on Sunday (Aug. 9), at the break of day, one of his brigades was concentrated with the corps artillery on the plateau of Riedisheim, and the other to the S. of Dornach.

The apprehensions of the commander of the 14th Div. were only too well justified. The German plan of concentration provided for the formation of an army under Gen. von Heeringen between Strassburg and Colmar. Two of the corps belonging to it, the XIV. and XV., were already mobilized and had practically finished their concentration on Aug. 7 when the Germans first heard of the audacious French advance. The smallness of the numbers opposing them caused the Germans no anxiety. They therefore made no attempt at resistance, but utilizing their roads and railways to the full assembled superior forces behind the Harth and Nonnenbruch forests. Thus on the morning of the 9th an armoured train of eight trucks, on which the French artillery fired unsuccessfully, went to and fro between Mülheim and the Ile Napoleon, bringing up infantry units on each trip. In a few hours hostile columns advanced from all directions, and by about 5 P.M. the VII. French Corps was

Reproduced by permission from the map of France on the scale of 1:200,000, published by the Service Géographique de l'Armée.

violently attacked all along the line by the superior forces of the XIV. and XV. German Corps. It held its ground till nightfall, and counter-attacking drove back the enemy on Rixheim and the Ile Napoleon, but was eventually forced to break off the action under cover of darkness to avoid envelopment. The artillery got away in good order, and despite the difficulty of disengaging the infantry in the darkness and in the enclosed country the withdrawal westwards was successfully effected without interference from the enemy. On the 10th order was established in the units of the VII. Corps, which on the morrow took up a position on the frontier behind the St. Nicholas.

If the French general staff had acted very imprudently by taking such an early offensive in the Sundgau that it could not keep it up, the German general staff showed singular indecision in not profiting by their superior numbers to follow up and overwhelm the French corps, as early as Aug. 10, and to attack Belfort during the confusion following its defeat. It held strictly to its plan of operations, and, having prepared a massed attack on Luxemburg and Belgium, provided for a strict defensive between Switzerland and the Donon. The XIV. and XV. Corps rejoined the army of von Heeringen on the 10th, and the defense of Upper Alsace was given over to Gen. von Gaede, who received for that purpose the command of four brigades of Landwehr. The organization of this detachment took time, and when the Landwehr at length undertook a tardy pursuit they had lost touch with the VII. Corps. Instead of marching towards the W. they advanced to the S., in the hope, doubtless, of being able to force the defile which formed the easiest approach to Belfort. But they had been forestalled in this direction by the garrison of Belfort (57th Div., Gen. Bernard), which on Aug. 13 checked their advance before Montreux-Vieux. Having lost during the day 1,800 to 2,000 men, the Germans suspended their counter-offensive, and fell back rapidly towards the E., abandoning arms, equipment, and munitions.

*The Operations of the Army of Alsace.*—As early as Aug. 10, however, Gen. Joffre, wishing to react against the effects of the repulse of Mulhouse, had decided to form an Alsatian army in the vicinity of Belfort under the command of Gen. Pau, which was to renew the advance in greater strength. It had also the mission of covering the right flank of the I. Army, which under the orders of Gen. Dubail, was to operate in the direction of the Donon, and the Bruche valley.

The Army of Alsace comprised the 8th Cavalry Div., five detachments of Chasseurs Alpins, the VII. Army Corps, the 44th Infantry Div. consisting of the troops from Africa, the 58th, 63rd and 66th Reserve Divs. from the centre and the S. of France, and the 57th Reserve Div. with two heavy batteries detached from the Belfort garrison.

Before all these formations had arrived the army took the offensive on the left; and the five battalions of Chasseurs crossing the passes of Bussang and Schlucht, which the Germans had abandoned at the beginning of August, descended towards Thann, Cernay and Colmar. The main body of the army advanced on the 16th, the advance being methodically executed with the idea first of cutting off the enemy's retreat to the N., then driving him back beyond Mulhouse, and either hemming him in against the Swiss frontier or forcing him back to the other side of the Rhine.

Disconcerted by a counter-offensive which they had not expected so soon, and by the superior numbers of their adversaries, the Germans under von Gaede fell back rapidly everywhere, offering little resistance. In three days all the territory to the S. of the Vosges was cleared, and at 10 A.M. on the 19th the main body of the Army of Alsace attacked the enemy forces concentrated before Mulhouse, their right at Lutterbach and Pfastatt, their centre at Dornach, their left towards Brunstatt. Fighting continued during the afternoon, being particularly severe around Dornach. The eventual capture of this village by the French decided the day, and the defeated Germans fell back towards the Harth and the Rhine, leaving behind them 24 guns and 1,000 prisoners. At 4 P.M., for the second time in a fortnight, the victorious French entered Mulhouse. They were again warmly greeted by their brethren of Alsace, who were inspired by this rapid return to hope that this time they were definitely freed from the yoke of the oppressor. In the joy of triumph they refrained from further advance, and the conquered Germans were able to fall back unmolested when a vigorous pursuit might have turned their defeat into an irreparable rout.

A second battle, without any definite connexion with that of Dornach, took place on the same day, Aug. 19, some distance to the S. of Mulhouse. The 44th Div., which covered the right flank of the Army of Alsace, was attacked, between Leumschwiller and Tagsdorff, by a German division which had been brought over from the other side of the Rhine. This division was beaten off and obliged to beat a hasty retreat; but the French division, which had paid dearly for its victory, had to be withdrawn in order to refit. On the 21st it was relieved by the 57th Div. which occupied Altkirch with advance posts on the right bank. The 14th Bde. of Dragoons, supported by two battalions at Hirsengen and Hirtzbach, extended the line to the right and completed the screen covering the Army of Alsace.

Fortune for the moment seemed to smile upon the French, but suddenly the situation underwent a change, and their hopes were dashed to the ground by the disasters of Sarrebourg, Morhauge and Charleroi. The withdrawal of the XI. Army had an immediate repercussion on the situation of the I. Army, which had to conform to the retreat of its left-hand neighbour. The Army of Alsace was in its turn affected by the general withdrawal, and by orders from G.H.Q. was broken up in order that its various elements might be allotted to other formations.

The 44th Div. was the first to leave on Aug. 22 to rejoin the I. Army. On Aug. 24 the 57th Div. was again placed at the disposal of the governor of Belfort, and had to abandon its position at Altkirch and fall back first to Dannemarie, and thence to the line Montreux-Vieux–Foursemagne–Fontaine. On the 25th Mulhouse was evacuated, and the VII. Corps together with the 63rd Div. was entrained in order to form the nucleus of the VI. Army, of which Gen. Maunoury was to take command. On the 26th, the 66th Div. was sent to Montbéliard with the 14th Bde. of Dragoons. The 58th Div. fell back to the Upper Thur valley, one of its brigades being left to occupy the mouth of the defile at Thann.

The Chasseurs battalions and the 8th Dragoon Bde. marched by Münster road to the crest of the Vosges. The bridges of Illfurth and of Aspach were destroyed, the canal sluices between the Rhône and the Rhine were blown up, and the two large viaducts on either side of Dannemarie station were cut. The disbandment of the Army of Alsace thus left the Sundgau once more clear of French troops, and abandoned to the mercy of the Germans. At the same time Belfort was left exposed and open to hostile attack.

*Renewed Offensive of the Belfort Garrison.*—The rôle assigned to Belfort in the French defensive scheme was to support the right wing of the armies resting on the Swiss frontier, and to command the gap by which the enemy might endeavour to penetrate between the Vosges and the Jura, in order to gain a decisive advantage by taking the French armies in reverse. It was a vitally important rôle, since if the Germans once secured the gap they might penetrate into the heart of France by Besançon and Dijon.

A vast amount of work had been done in the last 40 years in constructing, on the basis of the small fortress of 1870, the great stronghold of 1914. Much, however, remained to be completed. The work necessitated by the invention of armour-piercing shells dragged on endlessly, hindered by the want of funds and by manufacturing delays in the workshops, to which must be added the alterations caused by the progress of armament leading to a constant modification of the plans. The result was thus a miscellaneous array of old works and new forts with others still in the course of construction.

The forts Roppe, Bessancourt, Vesélois, Fourgerais, and Bois D'Oye were splendid modern or modernized works. On the other hand, the construction of the forts of Giromagny and Salbert had not even been begun; and La Chaux and Mont-

Vaudois, the reconstruction of which had just been undertaken, were half demolished and transformed into enormous building yards so that they were quite incapable for the moment of playing any part in the defence. As in all the French fortresses, there was not enough heavy artillery; the guns were good, but their mountings were out of date; and as these could only be fired from platforms which took a long time to erect, they had not the necessary mobility; the 1,000 rounds apiece which was allowed them was totally insufficient, and the method of firing, as then practised, did not allow them to make full use of their range. Altogether, the defence of Belfort in 1914 presented grave deficiencies, and the command had no illusions as to its inconveniences or dangers, but there existed no means of remedying them save by hasty makeshifts and by special alertness. Nevertheless, confidence reigned in the fortress, everyone there knowing that will, energy, and moral courage are the first essentials for the defence of a besieged fortress.

Despite this confidence, the days which passed between July 26 and Aug. 2 1914 appeared painfully long to the Belfort garrison, helpless as it was in face of the German raids, owing to the order to remain at a distance of 10 km. from the frontier, which prevented them from taking even elementary measures of precaution. As elsewhere, mobilization at Belfort was only commenced on the morning of Sunday Aug. 2, and it was extremely complicated, involving as it did the mobilization of both reservists and territorials and their incorporation into their units, requisitioning, transport, supply of provisions, and placing of the fortress in a state of defence.

The mobilization had been well prepared and was carried out with singular regularity; but the fact of troops being diverted from Belfort for the operations which were immediately undertaken in Alsace rendered difficult the normal organization of the garrison. This was to have been composed of an actual brigade of infantry with five battalions of the 57th Res. Div. (12 battalions of infantry, three groups of field artillery, and a company of engineers, and two squadrons of dragoons), 19 battalions of territorial infantry, 15,000 artillery, and 3,000 sappers, together with detachments of custom-house officers, foresters, telegraphic and postal operators, hospital orderlies, clerks, and depot personnel of the various arms, altogether about 75,000 men. As a matter of fact, a half-mobilized brigade of the 57th Div. was called away as early as the 6th, to take part in the first offensive on Mulhouse, then the other brigade of the division was sent forward when barely completed, and it was to the 57th Div., thus formed in the face of the enemy, under the command of Gen. Bernard, that there fell the honour of checking the Germans at Montreux on Aug. 13, after the retreat of the VII. Corps. Without a moment's respite the division then took part in the operations of the Army of Alsace, and it was only on the 26th, after this army was broken up, that it returned to the vicinity of Foursemagne under the cannon of Belfort. While the reserve division was thus engaged, the active brigade took part in front of the fortress at Félon and Lagrange. The rest of the garrison had been assembled, and as soon as its various units were formed they were set to work, in conjunction with all the men from 15 to 60 years of age not subject to military service, to push on with the works laid down in the scheme of defence.

The completion of this task was necessarily impeded by the fighting in which a part of the garrison was engaged during August; but thanks to the willingness of all the workers, the enormous undertaking was achieved by the time that the Army of Alsace was dissolved. The armament of the forts had been completed, numerous batteries had been constructed and armed, and munition depots had been organized. Centres of resistance, united by continuous lines of trenches, which were again covered by accessory defences, had been erected around Roppe fort, the fort and the village of Bessancourt, Fort Meroux, the spur of Oye Wood, the work of the Bambois, and Salbert hill. Finally the organization of the principal zone of defence had been strengthened by large inundations on part of the front.

In front of this zone other works had been undertaken with a view to strengthening the fortress, and towards Frais, Chèvrement and Bourogne. The works of Mont Vaudois were pushed forward, and in the fortress of Chaux itself, the dismantling of which had left the road from Montreux to Montbéliard open to attack, the parapets were rebuilt, concrete shelters constructed and every device utilized which could render the dilapidated work capable of effective action.

All this might have been reassuring, if the experience of a few weeks of warfare had not confirmed the insufficiency of French heavy artillery material, and the power of the German heavy artillery which had crushed the resistance of Liége, Namur and Longwy. On Aug. 25, there could be no possible doubt that if the enemy could approach near enough to Belfort to establish his guns 8 km. from the forts, the heart of the place would be bombarded and the forts themselves smashed before the artillery of the defence could fire a shot. Under the circumstances, at the very moment that the generalissimo was recommending a defensive based on the fortresses, it was manifestly unwise to uncover the most useful of them all by rapidly evacuating the Sundgau and breaking up the Army of Alsace instead of using a part of it to prepare, occupy, and defend strong defensive positions at important points. G.H.Q. might have need elsewhere of the VII. Corps, the 44th and 63rd Divs. and part of the cavalry, but it did not remove either the 57th Div. or the 58th or the 66th Divs., or the 14th Dragoon Bde., so that these formations together were in effective strength superior to the enemy, who had left in front of the Army of Alsace only Ersatz and Landwehr troops.

Instead of these troops being withdrawn, and dispersed over the area of Montbéliard-Foursemagne-Wesserling, they might well have been ordered to stand fast in the Sundgau. Even if Mulhouse appeared to be too distant, or too exposed a position to hold, a judicious use of field fortifications would at least have enabled them to cover Thann, and to establish between Altkirch and Heidwiller a strongly fortified centre, from which it would have been possible to control the road to Basle, the valley of the Ille, the railway and the canal, while the 14th Dragoon Bde. watched all the country in the direction of Ferrette, the Harth, Mulhouse and the Nonnenbruch.

Nothing of this kind was done, and von Gaede was thus able to reoccupy the Sundgau at his leisure. It was now to be feared —the bad news coming in from all sides appeared to justify all manner of fears—that the Germans would make a vigorous attack on Belfort, in order to destroy the pivot of the extensive withdrawal of the Anglo-French troops, which was now being carried out along the whole Swiss frontier to Belgium.

Under these conditions, knowing he had only his own resources to count upon for the defence of the gap, Gen. Thévenet, governor of Belfort, decided not to await the enemy's attack, but at once to assume the offensive, based on the fortress, so as to clear the immediate outskirts of the place and to maintain the initiative. His original plan was to push forward the active brigade and the 57th Res. Div. in front of the fortress, to carry out offensive reconnaissances on an increasing scale, to gain ground by infiltration, to organize the positions gained, and thus to establish, little by little, an effective barrier across the gap. To his mind, the advance should be sufficient to place Belfort beyond the range of the enemy's artillery, and to reduce the line to be held as much as possible by establishing it at the point where the Swiss frontier salient of Porrentuy reduced to a minimum breadth the practicable part of the gap—30 km.—between the Vosges and Switzerland. While this brigade and division were advancing, the governor proposed to employ the rest of the garrison on completing the defences of the fortress and the extension of its perimeter. He also proposed, while making the territorials coöperate with the available civilian labour in constructing these works, to carry on with their training so that they could be employed on the front when the occasion arose. This plan was immediately put into operation. The offensive reconnaissances in front of the fortress began as from Aug. 28 and from that date were pursued without interruption.

The 57th Div., moving forward from its position between Montreux and Fontaine, performed the rôle assigned to it with

remarkable energy. Its first reconnaissances were carried out by detachments of cavalry, patrols of infantry, and numerous squads of cyclists mounted on bicycles bought from the local shops, who pushed forward in every direction and drove back the small enemy detachments encountered by them. After Sept. 2 these reconnaissances were extended. Small columns consisting of one or two battalions, one or two sections of artillery, a few cavalrymen, and cyclists, repulsed the enemy in a series of engagements which were practically without exception successful. They appeared simultaneously in the direction of Falckwiller, Waldighoffen, Überkumen, Burnhaupt, Gildwiller, Sternemberg, Heimsprung, thus giving the illusion of a force very superior to that which the fortress of Belfort was in fact able to furnish. Thus covered, the 57th Div. was able to advance from village to village, organizing the localities as it occupied them, and on Sept. 10 the advance guards were on the line Ballersdorff–Gommersdorff–Tranbach beyond Dannemarie.

The active brigade had also carried out reconnaissances well in advance of its front Félon–Lagrange; on Sept. 6 it established its connexion with Thann, the most advanced point held by the 58th Div., which, since the break-up of the army of Alsace, had been bottled up in the Thur valley by the Germans, holding Cernay and the Nonnenbruch forest. On the 9th it advanced to the heights of the left bank of the Doller; its artillery broke up an attack of the 55th Brigade of Landwehr against Vieux-Thann, and at the close of the day it occupied Michelbach, Aspach-le-bas, and the important position of Kalberg, thus holding the highroad to Cernay, commanding the Nonnenbruch and overlooking the plain in the direction of Mulhouse.

After a day spent in massing strong forces at Cernay and in the Nonnenbruch, von Gaede on the 11th carried out a new demonstration against Thann, preceded by a bombardment, and directed a very violent, heavy attack against the positions held by the Belfort brigade. Despite serious losses, the latter held its ground; but its commander, feeling his position to be too exposed, and fearing to be cut off from the fortress, fell back under cover of darkness and regained his cantonments behind La Chapelle sous Rougemont.

It was not long before the advance of the 58th Div. on his right allowed him to push his advance guards forward to the Soultzbach, from Mortzwiller to Dieffmatten, while on his left Massevaux was held by a detachment which was supported in its turn by a Territorial battalion occupying the Ballon of Alsace, and the upper valley of the Doller.

On Sept. 18, wishing to put an end to the raids which the enemy patrols were still carrying out on his right, the governor of Belfort occupied Chavannate, Suarce, Lepuy and Réchézy with strong posts of custom-house officers, who from that day assured the safety of these villages.

On this same day, Sept. 18, the H.Q. of the 57th Div., whose daily reconnaissances had been carried on uninterruptedly in advance of its front, was transferred from Foussemagne to Dannemarie. This transfer was, from the point of view of the garrison of Belfort, the affirmation of their possession of this place, and it was completed on the day following the Marne victory, with the express intention of marking out a new permanent line of defence; it thus made a great impression in France, as also in Alsace, and had all the importance of a victory. It was indeed a considerable success, for the occupation of Dannemarie had been carried out with such precision and solidity that it had now to become definite. From Sept. 18 1914 onwards, the tricolor flag never ceased to fly over the little Alsatian town thus reconquered. (F. T.)

### (2.) The First Battles in Lorraine

The first plan of the French High Command, as shown in the General Instruction No. 1, of Aug. 8, was of a purely offensive nature; it was a question of seeking a battle, with all forces concentrated, with the right of the army resting on the Rhine. In Lorraine there were two French armies, the I. and II.; the I. Army was to move against the German Army of Saarburg (the VII.) and endeavour to throw it back in the direction of Strassburg and Lower Alsace. One isolated corps (the VII.) was to make a diversion to the E. of the Vosges; the II. Army, throwing out a flank guard to face Metz, was to take the offensive in the general direction of Saarbrück, on the front Delme–Château Salins–Dieuze, keeping touch with the I. Army in the region of the lakes. It was to leave its two left corps at the disposal of the generalissimo, in the area Bermécourt–Rozières en Haye (W. of the Moselle), with a view to their possible employment in the north.

In front of the I. and II. Armies were the VI. and VII. German Armies, the VI. (Prince Rupprecht of Bavaria) consisting at first of the I., II. and III. Bavarian, and I. Bavarian Reserve Corps and the XXI. Corps, together with two independent divisions and three cavalry divisions; the VII. (Gen. von Heernigen) of the XIV. and XV. Active and XIV. Reserve Corps and the 30th Reserve Division. Both armies were at first to remain on the defensive.

The extreme rapidity of the German invasion of Belgium, and the importance of this theatre, from the first moment induced the French High Command to hurry on the operations in Alsace and Lorraine in order to disengage the Belgian front. By Aug. 13 the VIII. and XIII. Corps were on the Meurthe, the XIII. in the triangle Baccarat–Raon l'Etape–Bazient, the VIII. in that of Fraimbois–Vathimenil–Gerbéviller. Gen. Dubail, commanding the I. Army, counted in addition on the coöperation of the two right corps of the II. Army [1] and on that of the XXI. Corps, descending from the Vosges on his right. On Aug. 16 the II. Cavalry Corps, with a division from the I. Army and two from the II., came under his orders.

It must be noted that the concentration, though completed as far as concerns the fighting troops, was to be entirely finished only on Aug. 18. However, the XIII. and VIII. Corps, commenced their movement on Aug. 14; the next day they entered Cirey and Blamont, driving back the I. Bavarian Corps, which, menaced with envelopment, retired on Saarburg. By the evening of Aug. 17 the two French corps had reached the line Vasperviller–Aspach–St. Georges, and the XXI. Corps was in line with them towards the Vosges. The II. Cavalry Corps had been ordered to lead the advance on Aug. 18 towards Saarburg, which fell into its hands after some fighting. The XXI. Corps pushed its advance guards north-eastwards to Walscheid; the XIII. held the heights N. and E. of Saarburg; the VIII. Corps, marching on Heming, seized the crossings over the Marne–Rhine canal and entered Saarburg. The II. Cavalry Corps bivouacked in the Diane Capelle area, in touch with the II. Army, which had reached the front Bisping–Château Salins on the left of the first. The Germans held strongly fortified positions facing the I. and II. Armies on a front of 37 m. from near Dommenheim to Biberkirch.

Both Gen. Dubail and his troops appeared full of confidence, as also did Gen. Joffre. It was decided that the I. Army should attack with its left N.W. of Saarburg, reposing its right and centre in view of the possibility of a German counter-attack in the Vosges, of which there were certain indications. The II. Cavalry Corps was to be directed on Saar Union and to operate to the S. of the Saar.

On Aug. 19 the left of the attack (VIII. Corps) commenced before daybreak, gained ground to the N.W. of Saarburg, despite the strength of the enemy's positions, and repulsed a counter-attack from the direction of Dolving. On Aug. 20 the advance was resumed, and early in the morning it became evident that the VIII. Corps would be unable to open the way for the II. Cavalry Corps. The 15th Div. could neither cross the Saar nor maintain its hold on Gosselming; counter-attacked from the N. it fell back on Kepprich and the wood to the E., then to the Marne–Rhine canal, after suffering severely from the fire of the German heavy artillery.

[1] The I. Army comprised at the beginning of hostilities the VIII., XIII., XXI., and XIV. Corps, the 12th, 13th, 22nd, 28th and 30th groups of Alpine Chasseurs, and the 71st Reserve Division. The XIV. Corps, the Alpine groups and the 71st Div. remained at first in the Vosges or at Epinal.

In the centre and on the right the French fared better. On Aug. 19 the XXI. Corps had extended its front to the S.E. of Saarburg, in the direction of Plaine de Valsch-Walscheid, without encountering any resistance; the XIII. Corps, which was in army reserve, had not yet been engaged. Next day the XXI. Corps, violently assailed by the XIV. German Corps, inflicted on it a serious defeat near Walscheid; the XIII. Corps, coming at last into line, attacked N.E. of Saarburg, disengaging the 16th Div. (VIII. Corps), which held the town till nightfall. Gen. Dubail's intention was to entrench himself astride the Saar on the front Kerprich–Soldatenkopf, and thence to resume a methodical advance foot by foot. But the defeat of the II. Army induced Gen. Joffre to order, on the evening of Aug. 20, the withdrawal of both armies. On the morning of Aug. 21 Gen. Dubail ordered the I. Army to retire slowly as far as Blamont. The withdrawal was carried out at first without serious difficulty, but was soon accelerated by the rapidity of the II. Army's retreat and by various untoward and costly incidents. On the evening of Aug. 22 the army, which had been joined by the XIV. Corps and 71st Reserve Div. from the Vosges, held a line from N. of Moudon forest to the Bonhomme pass; on the evening of Aug. 23 it had fallen back a good deal further, and, pivoting on its right, had thrown back its left to Damas aux Bois. At this point Gen. Dubail gave orders to stop the retreat and prepare for the resumption of the offensive. After this series of unfortunate movements the weariness of the French troops was extreme, and the infantry had suffered heavy loss—indeed in the VIII. Corps it exceeded 50% of the total strength.

The parallel offensive of the II. Army had been even less fortunate. Its mission was twofold: at all costs it was to protect Nancy, mainly because of the moral effect of the loss of that city; it was also to prolong the attack of the I. Army to the W., on the front Dieuze–Château Salins, with a flank guard facing Metz. The army, under Gen. de Castelnau, at first comprised the XVIII., IX., XX., XV., and XVI. Corps, three reserve divisions (59th, 68th and 70th) and two cavalry divisions. But in view of the necessity of parrying the German advance in Belgium by reinforcing the V. French Army, on the left of the line, the XVIII. Corps was sent north-westwards, on Aug. 13, to form Gen. Lanrezac's left. In the middle of the offensive, however, the greater part of the IX. Corps was sent off to reënforce the IV. Army. The two cavalry divisions were later incorporated into the II. Cavalry Corps and placed under the orders of the I. Army.

On Aug. 13, on the eve of the Lorraine offensive, the IX. Corps held the northern front of the Grand Couronné de Nancy,[1] with outposts on the Seille; the 70th Reserve Div. was towards Amance; the XX. Corps in the area Hueville–Laneuveville–Nancy, with forward troops on the Loutre Noire; the XV. Corps at Héraucourt, Drouville–Lerres–Courbessaux; the XIV. Corps at Lunéville–Xermaménil; the 59th and 68th Reserve Divs. in second line at Laxose and Vendoeuvre, and four Chasseurs battalions at St. Nicholas.

The generalissimo having prescribed that the I. and II. Armies should take the offensive, Gen. de Castelnau ordered the XVI. and XV. and the greater part of the XX. Corps to advance on Aug. 14 on Avricourt, the XX. Corps covering the northern front with the rest of its forces. On the evening of Aug. 14 the army held a line between Vuvrecourt and Goudrexon, facing N.E.; only the XV. Corps had met with serious resistance and been held up at Moncourt. Next day the situation of this corps, after the losses it had suffered, still checked further progress; the XVI. Corps advanced to Igney–Avricourt, the XX. to Bexange-la-Petite, Xanrey, and the northern edge of the Bezange la Grande forest; the IX. from its position on the Grand Couronné sent out detachments to Noméný, Bénicourt and Clemery. On Aug. 16 the German withdrawal continued, and the French followed rapidly; the XVI. Corps reached Mondange–Réchicourt–La Garde; the XV. Donnelay–Maremont; the XX. Vic–Moyenvic, the hills N. and N.W. of Donnelay; the IX. retaining its position.

On Aug. 17 the right of the II. Army was to swing up to the N.W., with the object of reaching the line Delme–Château Salins–Dieuze, the first objective fixed by Gen. Joffre. The XVI. Corps pushed forward without difficulty to the region Angviller–Bisping–Guerdemange; the XV. reached the Seille and occupied Marsal without resistance but failed to effect the passage of that river with its main body; the XX. Corps entered Château Salins and pushed reconnaissances northwards. The absence of the cavalry divisions was much felt at this time. Despite heavy night fighting at Rorbach, in which a fraction of the XVI. Corps was engaged, it was believed that the enemy was merely fighting rear-guard actions and that his main bodies were retiring, the I. Bavarian Corps on Saarburg, the XXI. and the left of the II. Bavarian Corps on Morhange.

Aug. 18 was to be given up to the crossing to the right bank of the Seille, but from the early morning the XVI. Corps encountered important hostile forces at the exits from the woods. On its right, the II. Cavalry Corps (I. Army) was not in position to support it, being itself held up at Dolving and Gosselming S. of the Saar. To the left the German heavy artillery pinned the XV. Corps to its ground on the Seille between Marsal and Zommange, preventing it even from occupying Dieuze. The XVI. Corps, being too far forward, was compelled to fall back on Angviller; only the XX. Corps advanced to the N. of Morville les Vic and Château Salins.

In spite of the departure of the IX. Corps, ordered on Aug. 18, to the IV. Army area, Gen. de Castelnau ordered on Aug. 19 that the offensive should be continued with the utmost energy, both to conform with the instructions of the generalissimo to hold fast as many as possible of the enemy in Lorraine, and in order to disengage the I. Army, now menaced by strong hostile forces from the direction of Phalsburg and Obersteigen. The XVI. Corps, while still continuing to cover the II. Army to the eastwards on the canal of Houillères, was to debouch from the region of the lakes to the N. of Loudrefing. The XV., operating to the E. of the Bride and Koeking forests, was to march on Bensdorf, and the XX. Corps, to the W. of these forests, on Morhange.

In order not to risk being taken in the flank by an attack from Metz, the II. Army was ordered for the moment not to cross the line of the Lower Albe below Bening Virming and Morhange. Thus the offensive of the right and not that of the left was limited, though the contrary was more natural.

On the morning of Aug. 19 the French right was checked by the enemy. As regards the XVI. Corps, the 31st Div. could not debouch to the N. of the Salines canal and had to be relieved by the 32nd; the XV. Corps captured Zommange and Vergaville, but could get no farther; only the XX. Corps made a considerable advance, reaching the northern edge of Château Salins forest, occupying Oron and pushing a brigade well forward on Morhange. The 68th Reserve Div., which had relieved the IX. Corps in its positions, covered the left flank of the XX. Corps very insufficiently at Fresnes en Saulnois–La Neuveville. The 70th Div., in the Seille around Manhoué, and the 59th on the Grand Couronné from Leyr to Ste. Geneviève, assured the immediate protection of Nancy. The enemy's intentions were still obscure.

In these circumstances Gen. de Castelnau deemed it advisable to clear the passages for the XVI. Corps over the Salines canal as soon as possible, and ordered that corps and the XV. to carry out a united attack on Aug. 20 against the line Cutting–Domnom–Bassing, and to drive back the enemy as far as the Saarburg–Bensdorf railway. The XX. Corps consolidated its positions taken the previous day, and prepared either to continue its advance to the N. or to the N.E., or to face any possible attacks coming from Metz.

On the morning of Aug. 20 mist delayed the offensive of the XV. and XVI. Corps, which were in fact later violently attacked themselves and checked and even forced back. The XX. Corps had received from its commander, Gen. Foch, orders inspired,

[1] A group of steeply sloping hills forming a semicircle around Nancy, on the E. bank of the Moselle.

it would seem, rather by the doctrine of the resolute offensive then in favour in the French Army than by the orders of Gen. de Castelnau; they laid down that the heights of Baronville and Morhange, reached the previous evening, should be secured and that the right should then endeavour to disengage the XV. Corps and facilitate its attack.

On Aug. 20 the 11th Div. attacked the front Morhange–Racrange, in conjunction with the XV. Corps; to the left, the 39th Div. the line Brehain–Baronville. About 6:30 A.M. Gen. de Castelnau stopped this offensive, which he considered inopportune, and ordered that the right of the XX. Corps should support the XV., while the left should hold and fortify the position then held by it and should even prepare a second position farther south. But these arrangements were upset by the enemy taking the offensive; the left of the XX. Corps (39th Div.), heavily assailed, had to retire on Château Salins, involving the withdrawal of the right (11th Div.), which fell back on Lidrequin, and of the 68th Reserve Div., which withdrew from Lenoncourt to its position of Aug. 19. The situation of the II. Army became so perilous that at 4 P.M. Gen. de Castelnau ordered the retreat. The corps were moved away that night, with the intention of re-forming their most sorely tried units farther south; rear guards facing N.E. from Maizières to Fresnes en Saulnois were to cover the withdrawal.

These movements were carried out that evening and night, and during Aug. 21, under the protection of the XX. Corps and the 68th Reserve Div., which had orders to hold on to Château Salins as long as possible and to fall back thence on St. Nicolas. The remainder of the army reached the area Dombasle–Lunéville, and were there reënforced by two reserve divisions, the 64th and 74th; the 73rd Reserve Div., forming part of the mobile garrison of Toul, moved to the N.W. of Nancy, and the II. Cavalry Corps (less the 6th Cavalry Div. which was left under the orders of Gen. Dubail) was on Aug. 22 transferred from the I. to the II. Army and was ordered to cover the latter's right. The enemy at first followed slowly, but soon violently attacked the XVI. Corps at Crion and Lionviller, and forced it back over Lunéville, whence it went back to reform in the Xermaménil area. Finally, while the XX. Corps was waging a series of successful actions in the heights of Flainval, before retiring on St. Nicolas, the remainder established themselves on the W. bank of the Meurthe, the XVI. Corps holding the hills of Belchamps, the 74th Reserve Div. astride the Lunéville–Bayon road, the XV. Corps at Haussonville and Ferrières, and the 64th Reserve Div. in the Sappais plateau. The Grand Couronné was still held by the 18th Div. (IX. Corps), the dispatch of which to the S. had been delayed, and by the 59th and 68th Reserve Divisions. The offensive of the II. Army, as well as that of the I., had thus been a complete failure. Various factors contributed to this result, the most important being the French inferiority in material and the insufficient preparation of the attacks.

Meanwhile the I. Army also had stopped its retreat. On Aug. 23 Gen. Dubail laid down that its mission henceforward would be to forbid any new hostile advance and refit so as to be in a condition to resume the offensive in the near future; it was also to support the II. Army, which was being heavily attacked, on its left. This was the object of a three weeks' battle, the first act of which was to take place on the Mortagne. On Aug. 23 Gen. Dubail ordered the VIII. Corps, supported on its left by the cavalry division, to operate against the flank of the Germans then attacking the right of the II. Army. The VIII. and XIII. Corps, forming the I. Army's left wing, were holding the line Damas aux Bois–Anglemont.

On Aug. 24 the II. Army was attacked on the front Haussonville–Borville. The VIII. Corps was directed to take the offensive in the direction of Veney–Moriviller, while the XIII. Corps, covering its right, moved to the vicinity of Ménarmont, ready to face N. or E. according to circumstances. These movements, carried out on Aug. 24 and 25, were of considerable assistance to the II. Army, before which the enemy fell back on Aug. 26 to the north-east. Next day the VIII. Corps reached the Mortagne, but from Aug. 28 to Aug. 30 it could do no more than repulse the enemy's attacks, without itself getting forward. On Aug. 30 and 31 the Germans, entrenched to the E. of the river, on the heights of Domptail, held up the French advance, but were themselves unable to make any progress. The utility of the VIII. and XIII. Corps' action was all the greater, as at this time the II. Army was being heavily assailed, first in the direction from Lunéville to Charmes, and then in the Grand Couronné. It appears, indeed, to have been the Germans' first intention to advance with the VI. Army along this former line, and with the VII. by Raon l'Etape and Rambervillers on Charmes; their common effort being directed to forcing what is usually known as "the gap of Charmes." The I. Army was further weakened by the departure from its position on the right of the XIII. Corps, and of the XXI. Corps, which left to join the IV. Army in Champagne, arriving there in time to take part in the last days of the battle of the Marne.

From Sept. 5 to 7 the VIII. and XIII. Corps merely maintained their positions. On Sept. 6 the German VII. Army, which faced the French I. Army, was dissolved by order of the supreme command. Two of its corps joined the VI. Army, now left alone in Lorraine; the staff and one corps were sent W. to reënforce the German right wing, heavily engaged with Maunoury (French VI. Army) on the Ourcq. On Sept. 7, as the enemy in front of the VIII. and XIII. Corps seemed to be weakening, an attempt was made to resume the French offensive; and on Sept. 9 the VIII. Corps was ordered to capture St. Pierremont and Magnières by a night attack; the XIII. Corps and a provisional corps formed of troops already on the army front, and put into line in place of the XXI. Corps, were also to attack farther to the east.

The operation thus projected was a success only on the right and in the centre; the VIII. Corps attack failed. At this moment the I. Army was still further and more seriously weakened by the arrival of orders for the transfer of the XIII. Corps elsewhere. While it was being transported to the W. of the Oise, where it was to prolong the left of the VI. Army, the I. Army consolidated its recent gains. On Sept. 12 the VIII. Corps attacked towards Domptail and Azerailles, and the 71st Reserve Div., which had replaced the XIII. Corps, towards Baccarat, and the provisional corps towards Raon l'Etape. By the evening the I. Army had reached the Meurthe; unfortunately the pursuit was stopped by another transfer, this time of the VIII. Corps on Sept. 13 to St. Mihiel on the Meuse, where another German offensive was being prepared. The left wing of the army (71st Reserve Div. and provisional corps) took up position along the Meurthe from Raon l'Etape to Azerailles. The fighting known as the battle of the Meurthe now came to an end.

Meanwhile the XXI. and XIV. Corps, on the right of the I. Army astride the Meurthe, had also attempted to carry out the mission assigned to them by Gen. Dubail, to stop the enemy's advance, and prepare for a resumption of the offensive. Their first efforts met with little success; in fact, up to Aug. 27 they had lost ground; and the 44th Div., which was being brought up from the Vosges to reënforce the I. Army's left, had to stop and support them (Aug. 25). On Aug. 26 the right of the XIV. Corps was driven back in the Ban de Sapt; next day, the enemy entered Ste. Dié, and the withdrawal of the 58th Reserve Div. from Anozel pass uncovered the eastern flank of the XIV. Corps, which fell back from Nompatelize and then from La Bourgonce (Aug. 29). The Germans endeavoured to cut off the corps from the Vosges and menace the I. Army's right flank; and successful though costly counter-attacks by the XIV. Corps on Aug. 30 recovered both Nompatelize and La Bourgonce. On Aug. 31 and Sept. 1 its right maintained itself at Anozel; on Sept. 3 the corps held a line thence to Rougiville and the N. edge of the forest of Mortagne, but its situation remained anxious up to and including Sept. 6. Not till Sept. 7, when the army had consolidated its line in the Vosges, could the XIV. Corps make a little progress; it then accentuated its offensive, reoccupied Ste. Dié on Sept. 15 and reached the Meurthe along its whole front, as the VIII. Corps, the 71st Reserve Div. and the provisional corps had done. By this time the Vosges

group" had got into definite touch with the right of the XIV. Corps from the Bonhomme pass. The I. Army had been successful in fixing important enemy forces on its own front, and in bringing considerable relief to the rest of the French line, despite the fact that many men had been withdrawn from it to reënforce those armies to whom decisive rôles had been assigned.

The II. Army also had passed no less difficult days. On the morning of Aug. 21, after the defeat of Morhanges, Gen. Joffre wired, "The II. Army will endeavour to reconstitute and hold fast on the Grand Couronné and on the Meurthe and the Moselle." Gen. de Castelnau decided therefore to maintain at all costs the Grand Couronné and the line held by the XV. and XVI. Corps and the 64th and 74th Reserve Divs., while holding the rest of the army ready for a counter offensive in the area of Lenoncourt. But the situation rapidly changed, and it fell to Gen. de Castelnau's lot to prepare, not a counter-attack but an attack.

Early on Aug. 24 it was reported that at least two hostile corps were moving southwards, exposing their right flank to the II. Army. Gen. de Castelnau, seizing his opportunity, ordered an advance in the direction of Serres by one division of the XX. Corps and the available troops of the reserve divisions holding the Grand Couronné. The XVI. and XV. Corps, the 64th and 74th Reserve Divs. and the rest of the XX. Corps, were to contain the enemy in front, the II. Cavalry Corps covering their right. The VIII. Corps on the left of the I. Army was requested to coöperate by advancing on the front Rozelieures–Vennezey, in a direction almost at right angles to the II. Army front. Thus ensued the battle of Aug. 25.

Gen. de Castelnau's objective was Arracourt–Einville, which appeared to be the enemy's line of communication from the north. The main attack was to be supported on the right by the XVI. and one division of the XV. Corps, in concert with the VIII. Corps. But it soon became clear that the last-named formation would not be able to debouch to the N. of Essey and St. Boingt, and it became necessary to make the action of the II. Army more prompt and more intense. The II. Cavalry Corps, the XVI. and one division of the XV. Corps, were pushed forward, driving the enemy back to the E. of Rozelieures; at nightfall the XVI. Corps was in possession of this village and the XV. of Lamath and Blainville, while the main body of the II. Cavalry Corps was moving on Deinvillers. On the French left, progress, rapid at first, had been checked by a strong counter-attack on Flainval; by evening, however, the XX. Corps held the heights of Sommerville, Flainval and Hudiviller with its 11th Div. and its 39th Div. remaining in the region of St. Nicolas. To the N., portions of the IX. Corps and the 68th Reserve Div. held the eastern edges of the forest of Champenois.

After the battle of Aug. 25 Gen. de Castelnau proposed to seize the passages over the Meurthe S. of Lunéville, and then to advance on the Einville–Arracourt road by attacking between the Meurthe and the Sanon and by seizing the heights of Serres. The fatigue of the troops, who had been marching and fighting continuously since Aug. 14, was the first cause of difficulty; and since the left centre and right of the I. Army were violently attacked one after the other, the II. Army had to manœuvre by its right, while refusing its left, and the offensive on Serres could not be carried out with the necessary vigour.

However, in the course of Aug. 21 the II. Army made some progress. The XVI. Corps reached Remenoville and the XV. occupied Mont sur Meurthe, but could get no farther. The XX. Corps got as far as the line Friscati (N.W. of Lunéville)–Deuxville–Maixe, prolonged to the left by the 70th Reserve Div. which held Drouville. To the N. the 18th Div. (IX. Corps) maintained its positions in the area Courbessaux–Reméréville–Champenois.

On Aug. 27 the XVI. and XV. Corps, to which the 74th and 64th Reserve Divs. were attached, fought a series of successful actions at Xermaménil and Blainville. The rest of the army remained halted. On Aug. 28 its right undertook a general offensive, with the idea of reaching the Meurthe, but the XVI. Corps and the 74th Div. after capturing Gerbéviller were held up and finally driven out of the town and back to the Mortagne. The XV. Corps was checked at the St. Mansey wood, between the Mortagne and the Meurthe, and did not push its left towards Vitrimont forest, while the XX. Corps made little headway N. of the Meurthe.

On Aug. 29 the XVI. Corps retook Gerbéviller, but was then checked all day in frontal fighting, which also delayed the advance of the XV. Corps on the Meurthe. Aviation reports stated that the enemy was preparing a second line of defence, facing the French left, and was evacuating the first line, which seemed to indicate that he was growing weaker. Gen. de Castelnau therefore decided to attack on Aug. 30 between the Sanon and the Nancy–Château Salins railway, and to take and consolidate the Serres heights. However, in view of the violent hostile attacks against the I. Army, the plan had once more to be modified, and again the II. Army was driven to manœuvre by its right in conjunction with the I. Army. On Aug. 30 the principal action took place around the clearing of Fraimbois, S. of Lunéville, between the Meurthe and the Mortagne. The XVI. Corps and 74th Reserve Div., despite their losses, failed to take Fraimbois, but to the N. the XX. Corps occupied the signal of Frascati. On Aug. 31 the enemy's attacks on Rehainviller (S.W. of Lunéville) were repulsed, and the French consolidated their positions.

It was not till Sept. 1 that Gen. de Castelnau could resume the manœuvre originally planned for Aug. 30; he ordered that on this date the army should attack between the Meurthe and the Sanon, and take and hold the heights N. of Lunéville. The XX. Corps was only partially successful in reaching its objective, and on the rest of the front the positions were unchanged.

The situation of the II. Army had by this time considerably changed. Gen. Joffre intended eventually to resume the offensive on the centre and left of the Allied armies, but did not believe that the opportunity would come as it actually did; he therefore deemed it necessary to withdraw troops to the fullest extent from his right-wing armies, which were not called on to play a decisive part in this manœuvre. On Sept. 1 orders were issued for the westward move of a cavalry division and a Chasseur brigade; on Sept. 2 the 18th Div. (IX. Corps) and the XV. Corps were also sent off. In view of this additional weakening the II. Army seemed condemned to the defensive.

Moreover, at this moment, the fighting before Nancy necessitated new and great efforts on the part of that army. On Sept. 4 the enemy's activity became more intense on the Meurthe and in the Serres area, and towards evening they opened a bombardment on all the front between Vitrimont forest and Courbessaux. Emperor William II. had arrived from Metz with the intention of making a triumphal entry into Nancy in a few days' time. The Germans possessed an immensely powerful heavy artillery and did not hesitate to employ it to the fullest possible extent; on the night of Sept. 5–6, in eight hours, over 3,000 shells fell on the hill of Amance in an area of little over 1,000 sq. yards.

By Sept. 5 both Gen. Joffre and the commander of the II. Army had appreciated to the full the seriousness of the situation. For a time they hesitated as to whether they should withdraw the army's left to the strong positions of the forest of Haye and the heights of Sappais and Belchamps S.W. of Nancy, or hold the line in front of the city at all costs. This hesitation seems to have lasted right up till Sept. 7; fortunately the second plan was adopted and carried out.

During the battle of Nancy, the French right, the XVI. Corps, the 74th Reserve Div., the XV. Corps and the 64th Reserve Div., fighting in the area Rehainviller–Xermaménil–Gerbéviller, maintained their positions practically intact from Sept. 6 to 11. In the centre and on the left, however, the fighting was extremely fierce, and the French line swayed to and fro, from the Sanon to the northern edge of Champenois forest.

On Sept. 5 the enemy seized Maixe and Reméréville, but lost the latter place again in the evening, and failed to dislodge the French from the eastern edge of Champenois forest. On Sept. 6 the 39th Div. (XX. Corps) attacked and reoccupied

Crévic and the wood of the same name. Next day a German force advancing from Pont à Mousson violently assaulted the N. front of the Grand Couronné; the commanding village of Ste. Geneviève was for a time evacuated, but was reoccupied by the French on Sept. 8, 2,000 enemy dead being counted on the ground. On Sept. 7 also another attack was delivered on the eastern front in the direction of Mont d'Amance and Laneuvellotte, and the 68th Reserve Div. fell back into the defile of La Bouzule between the two ridges in Champenoux forest. The French line was forced back to its western edge, and had also to be withdrawn from the forward positions to the S., towards Courbessaux and Drouville.

The German attacks continued in the night of Sept. 7–8, and on Sept. 8, but on neither occasion did they meet with any success. Violent fighting occurred on Sept. 9 on the western border of Champenois forest, but the French maintained their positions. To the S., in order to relieve the pressure on the 59th and 68th Reserve Divs., the XX. Corps undertook an offensive in the direction of Drouville and Courbessaux; some ground was gained, including Crévic wood, which had previously been lost, and the French line was pushed forward to the centre of St. Paul forest. Gen. de Castelnau ordered a vigorous offensive on Sept. 10, by the 59th and 68th Reserve Divs., in Champenoux forest and on the Bouzule, by the XX. Corps on Reméréville, and by the XVI. Corps towards Lunéville; although the results achieved were incomplete, the enemy's resistance appeared to be weakening all along the line, and on Sept. 11 the French succeeded in retaking the eastern edges of Champenoux forest, St. Paul forest and Haraucourt wood. Next day it was learnt that the Germans were retiring, abandoning large quantities of arms and ammunition at Lunéville; the left of the I. Army was advancing northwards without encountering any resistance. The II. Army began the pursuit on its front, occupying Fraimbois, Lunéville, Drouville, Courbessaux, Reméréville, Nomény, and Pont à Mousson; the cavalry pushed forward to Einville, Serres and Morville.

On Sept. 13 the French occupied the heights of Crion and Sionviller, and those to the N. of Serres, together with the wood to the W. of Sornéville. The I. Army's left was at Vathiménil, and the line of the Meurthe had thus been definitely and completely secured, never again to be lost. Meanwhile another German offensive was in preparation W. of Nancy, in the Woevres and on the Meuse, and the II. Army had to dispatch in this direction to meet it, first the 2nd Cavalry Div., then the 73rd Reserve Div. from Toul, and finally, on Sept. 13, the XX. Corps. This new development brought to an end the pursuit which had been begun after the battle of Nancy, and in a few days the II. Army was broken up, to be reconstituted anew on the left of the French VI. Army during the "race to the sea."

Thus, after a difficult beginning, with a defeat resulting from an inopportune offensive, the I. and II. Armies had been successful at first in checking the enemy's progress, and then in driving him back practically as far as the former French frontier. Their rôle, in itself no easy one, had been rendered even more difficult owing to the constant weakening of their effectives by the removal of their best elements to other parts of the front. During the battle of the Marne they formed the unshakable pivot of the centre and left of the Allied armies, and freed them from all anxiety as to their right flank. If, thanks to the memorable initiative of Gen. Galliéni, Gen. Joffre succeeded in carrying out on the Marne and on the Ourcq the manœuvre which caused the enemy's retirement to the Aisne and completely ruined his original plan of campaign, it was because of the efforts and sacrifices of the I. and II. Armies. By holding fast on the Meurthe and before Nancy, three hostile corps and numerous reserve formations, the II. Army had fulfilled, as had the I. at the foot of the Vosges, a task indispensable to the strategic reestablishment of the whole of the Allied forces. The price had unhappily been a great one. Between Aug. 24 and Sept. 22 the 74th Reserve Div. (to take only one example) lost 140 officers and over 5,000 other ranks, practically a third of its effective strength, and the casualties in other units had been even heavier. (B. E. P.)

### (3.) Battle of the Ardennes

Directly the large concentration transports, which were at their height from Aug. 8–14, began, the III. French Army was formed in the region of Verdun under the protection of the VI. Army Corps, which took up protective duties on July 31 1914. Gen. Ruffey, with Gen. Grossetti as his chief-of-staff, was in command. On Aug. 14 that army consisted of the IV. Corps, to the E. of Damvilliers; the V. Corps, to the W. of Etain; the VI. Corps in the Woevre to the E. of Fresnes-en-Woevre, Vigneulles and St. Baussant. A group of reserve divisions, commanded by Gen. Pol Durand, was then under the orders of Gen. Ruffey, but they were not all completely disembarked by that date (Aug. 14). The 7th Cav. Div. (Gen. Gillain), attached to the III. Army, covered the right wing of that army towards Metz.

The IV. French Army was at first designed to form a general reserve in the hands of the general-in-chief; and, with a force of three army corps and one cavalry division, was grouped in the region between Vitry-le-François and Ste. Menehould. But on hearing of the German attack on Liége Gen. Joffre decided to send the IV. Army in the first line, to the left of the III. Army, in the region of Stenay (Aug. 8 1914). The II. Corps, which protected the V. Army to the E. of Stenay, as did the VI. Corps to the E. of Verdun, remained on the spot, while the V. Army (Gen. Lanrezac) returned farther to the N.E., first in the region of Vouziers–Auberton, and then towards Charleroi.

Directly it entered the lines the IV. Army—commanded by Gen. de Langle de Cary, with Gen. Maistre as chief-of-staff—was considerably reënforced. The II. Army Corps was the first to join it, followed by the XI. and IX. Corps, and the 52nd and 60th Reserve Divisions. In the Ardennes the 4th and 9th Cav. Divs. were at its disposal. This IV. Army was, on Aug. 22 1914, by far the strongest of all the French armies.

According to Plan 17, which regulated the concentration operations, there would be little more than protective corps on the frontier until Aug. 8. Between Aug. 8 and 14 the concentration transports, working with their maximum efficiency, were to bring all the army corps stationed in the interior to the concentration zone of their armies. It was not before Aug. 15 or 16, therefore, that Gen. Joffre would have all his resources at command. But the general-in-chief was determined to keep to the defensive, even a yielding defensive, which would be willing to lose ground until the concentration of all the French forces had been effected. Owing to this decision the protective corps formed a rigid cordon, with only very small detachments—rifle and cavalry battalions—ahead of it.

On the other side the Germans were proceeding in the same way. They were determined to fight with extreme violence everything that opposed the bringing into position of their armies, but would make no efforts to thwart the enemy's concentration, or even to know how the French High Command organized its distribution of forces.

It is not surprising, therefore, that the first great battle was the "battle of the two blind men." Neither belligerent knew exactly where the encounter would take place, nor what forces they would have to fight. On Aug. 10 1914, when the IV. Army Corps had only just joined the lines, to the left of the IV. Army, a German mixed brigade, starting westwards at a venture from Thionville, had the mad idea to attack at Mangiennes, the spot where the junction of the III. and IV. Armies was taking place. Without thinking, it engaged *à fond*. Then it was that Gen. Cordonnier came and took this brigade in reverse, after it had already been roughly handled in the frontal attack, and destroyed it. The Germans did not try to avenge their defeat; they made no further attempt against the protective troops of the III. and IV. Armies. The Germans were absorbed in the deployment of their armies: the V., to the W. of Thionville as far as Tintigny; the IV., from Tintigny to Dinant; the III., from Dinant towards Charleroi; the II., on the Sambre; the I., towards Mons, in accordance with a plan mathematically determined in the pre-war period.

The French, bringing into play the variant which placed their IV. Army between the III. and V. Armies, formed up ladderwise. If the III. and IV. Armies faced eastwards, the VI.

Corps served to form the highest rung, while the lowest was occupied by the IX. Corps. If they faced N., the lowest step would be the VI. and V. Corps, then the IV., then the II.; such would be the following steps, each rising higher and higher.

When Gen. Joffre launched his rigid formation brutally to the N., the German deployment was not yet effected; thus it was that the German III. Army, entangled behind the IV. Army, did not appear upon the battlefields of the Ardennes; it was a wasted force. The offensive, which drew such criticism against the French general-in-chief, thus produced this happy result, that a battle was brought about at a time when the enemy could not avail themselves of all their resources.

The battle of the Ardennes was to take place between the French III. and IV. Armies on the one side, and the V. Army, commanded by the German Crown Prince, the IV. German Army, under the Duke of Württemberg, and the III. German Army, under Gen. von Hausen, on the other; but the German III. Army was not destined to fire a single gun, either against Gen. de Langle de Cary's troops, or against those of Gen. Lanrezac; its cavalry alone took part in the Dinant skirmish.

On Aug. 16 1914 Gen. Ruffey's army moved slightly northwards. The IV. Corps advanced to Jametz, the VI. Corps pushed forward as far as Etain, the V. Corps took up its position between these two localities. As this army left the Hauts-de-Meuse region it was replaced by the reserve divisions of Gen. Pol Durand. Fresh reserve divisions arrived shortly, and on Aug. 19 they formed the Lorraine army, under Gen. Maunoury. The mission of the Lorraine army—which consisted of the reserve division groups of Gens. Pol Durand and Beaudenom de Lamaze and the mobile reserve divisions of Toul and of Verdun—was to invest Metz, should the III. Army be victorious near Longwy; its defensive mission was to stop any German troops attempting to force the Hauts-de-Meuse.

The Lorraine army was not under Gen. Ruffey, but it covered the rear of the IV. Army. No army, when fighting is carried on in the same theatre of war, is truly independent; each must communicate with and help its neighbour as far as possible. This solidarity was not to be found to a desirable degree between the III. Army and the Lorraine army; but if one realizes that, in spite of its small population, France managed in Aug. 1914 to face the Germans with forces nearly equal to those of the Kaiser's army, it is easy to understand that the French reserve divisions were composed of elderly men, slow to acclimatize to war, and that their *cadres* and staffs needed considerable time to acquire the desirable manœuvring qualities.

On Aug. 20 1914 the French III. and IV. Armies faced N.; they were ordered to keep in touch with each other on the axis Marville–Virton–Etalle, during the advance northward. They formed a strict whole, and yet there was no army group commander to impart unity to this ensemble.

To the right of the bloc was the VI. Corps, whose direction of attack was the neighbourhood of Audun-le-Roman and Longwy. This army corps, commanded by Gen. Sarrail, consisted of three divisions, and was to advance in échelon and to the rear of the V. Corps with two divisions, while the third was to be a flank guard, facing the fortified region Metz–Thionville.

The Lorraine army, as has been said, prolonged the flank guard of the III. Army through the Woevre to Toul; in the E., it was in touch with the II. Army (Gen. Castelnau). Thus in proportion as one advanced farther W. the initial dispositions gained ground towards the north. At the extreme left the IX. Corps was disembarking near Mézières–Sedan; taken away from the French II. Army it retained only one of its divisions, the J. B. Dumas Div., which, even before all its troops had been able to join it, was to launch advanced guards between the Semoy and the Lesse. A Moroccan division was soon to reinforce the IX. Corps. Gen. Lanrezac was obsessed by fears for his right flank, whereas his real danger lay in front and on his left flank. By a spirit of *camaraderie* for the commander of the V. Army, Gen. de Langle de Cary sent advanced guards, disposed somewhat at random, to occupy Gedinne, Houdremont and Bièvre; the 60th Res. Div. was ordered to hold the crossings of the Semoy, from below Bohan to its confluence with the Meuse at Monthermé, while the 52nd Res. Div. was to keep watch on the Meuse as far as Revin, where the operation zone of the V. Army began. The 4th and 9th Cav. Divs., forming one cavalry corps, reconnoitred in front of the IX. and XI. Army Corps, to the left of the IV. Army; and the 7th Cav. Div. reconnoitred to the right of the III. Army. On Aug. 22, on the extensive front from Bertris to about Audun-le-Roman, there was only the cavalry of the French army corps.

In the night of Aug. 20–21 the whole French system moved forward; the day's march was long for all; for some it was a forced march. The only instructions given by the French High Command were "to attack the enemy wherever they were encountered"; and as the marching directions were prolonged very far northwards in the orders many unit commanders supposed the enemy to be far in the north. Although, here and there, they came violently into touch with the enemy, as for instance the 9th Cav. Div. at Neufchâteau, that was not enough to raise the alarm; and the following day, in the night of the 21st to 22nd, the same illusions caused the same imprudences to be repeated. The advance was all the more unhesitating in that it was expected that the enemy would be caught manœuvring. The Germans were not ready; von Kluck's great enveloping movement was only in a fair way of being carried out; von Hausen's army had not yet disengaged from the right of the Duke of Württemberg's army. Hence the sole task of the German army was to remain in readiness behind the trenches it had dug for itself.

One of the belligerents was waiting along a large battle-line extending from the Moselle, near Thionville, to the Meuse near Dinant. The other was advancing in countless columns, along all the roads leading from S. to N. between the Moselle and the Meuse. Engagements might be expected between cavalrymen everywhere, then between advanced guards and outposts; neither side would be surprised. Division battles would take place side by side with one another, thus forming one great battle without any break on the front, since the III. and IV. Armies were contiguous. The IV. Army was to push ahead; the III. Army "to cover the right flank of the IV. Army against forces which might still be in the Luxemburg region."

On Aug. 21 the higher formation vanguards of the IV. Army were on the Semoy, and between Semoy and Lesse on the left; but the vanguards of the II. Corps were farther S., at Meix-devant-Virton, the cavalry regiment only being at Bellefontaine. On the evening of that same day the III. Army reached Virton with the IV. Corps, Tellancourt with the V.; as for the VI. Corps, although its most advanced division was at Beuzeville, its 40th Div. (Gen. Hache) occupied Monaville in the rear, facing Briey, forming a flank guard to the 54th and 67th Res. Divs., disposed in échelon relatively to the 40th Division. The IV. Army had been engaged in action, and reported strong enemy forces to be in the Neufchâteau region; the III. Army declared it had seen no other enemy than a few small detachments, whereas the whole army of the Crown Prince of Germany was within its reach.

The orders for Aug. 22 were as follows: The IV. Army was to advance northwards and the III. Army was to cover the right of the IV. Army and face any attack from the N. and the E. Two of Gen. Pol Durand's reserve divisions were to occupy Spincourt and Monaville, by 8 o'clock on the 22nd, and be ready to counter-attack "everything that debouched from Briey."

Directly it debouched from Virton, the left division of the IV. Corps was driven sharply back to the S. of the Basse-Vire. Thus, as early as the morning of the 22nd, the III. Army failed in its mission to cover the right flank of the IV. Army; it knew nothing of the enemy, and its cavalry division remained inert. Badly commanded, it did nothing on that day, and neither its army commander nor the commander of the VI. Corps brought it into action. The V. Corps neglected to put itself in touch with the IV., and stormed the enemy positions without making use of guns to support the infantry. This soon led to a panic, and Gen. Grossetti was obliged to take the place of the army

FRONTIERS, BATTLES OF THE (LORRAINE)

PLATE II.

corps commander to restore order in this large unit where whole regiments retreated without fighting. The left division of the VI. Corps, while attempting to cross the Chiers at Cons-Lagrandville, was soon drawn into the retreating movement of the V. Corps. The centre division, which knew nothing of the enemy, engaged badly and was unable to progress farther than Ville-au-Montoir. The right division, stationed on the Fillières–Mercy-le-Haut front, facing Audun-le-Roman, and badly served by the reconnaissance service of the 7th Cav. Div., which forgot it was not alone, was attacked towards noon by the three divisions of the German XVI. Corps. But Gen. Hache, an able tactician, was there, and although both the cavalry division and the reserve division which should have protected his right and rear abandoned their post, he managed to make head against forces three times stronger than his own.

A lack of coöperation and of understanding had made itself felt between the Ruffey and Maunoury armies, due perhaps to a faulty transmission of orders. By the evening of the 22nd the III. Army had retreated on the Virton–Spincourt front.

In the IV. Army, the leading division of the II. Corps, warned by the corps cavalry regiment which had spent the night in a state of readiness near Bellefontaine in touch with the German positions and had identified their forces, deployed and got into touch with the enemy by its patrols. It expected its artillery to debouch N. of the woods. At about 9 A.M. the enemy attacked the French advanced guards, whose artillery had not yet appeared; but thanks to the woods and the preparations for defence of the village of Bellefontaine these first attacks were not successful. After 10 o'clock the advanced guard was reënforced by two groups of 75-mm. guns, and from that time was mistress of the situation; attacked at nightfall by a whole German army corps, it had lost no ground whatever at the end of the day; it had fought "like a lion."

Owing to the reverse of the IV. Corps at Virton, a gap had formed between the IV. and III. Armies at Villers-la-Loue. But fortunately, on the preceding day, Gen. de Langle had withdrawn the 3rd Div. from the front and disposed it in second line, behind his right. A division of the IV. Army, actuated by Gen. Gérard, the commander of the II. Corps, was thus at hand to ensure the *liaison* between the two armies. This saved the day. On Aug. 22 the II. Corps took part in two battles, separated by the large forest of Virton, at Bellefontaine and at Villers-la-Loue; both battles resulted in the defeat of the V. and VI. German Army Corps, and prisoners belonging to five different German divisions were taken. On the left of the II. Corps the Colonial Corps advanced on Rossignol in two columns; one mixed brigade on the left and one division on the right. The Ravenez Div., in column without advanced guard or flank guard, was crushed under the German projectiles to which it served as an extensive target. Its commander collected some remnants of his troops and rushed upon the enemy, gun in hand. He was killed, and "all was lost, save honour."

It is difficult, in that forest district, to make the most of a success; the Germans did not pursue their attack; so, by the evening, the Colonial Corps still held the Semoy and its outlet N. of Florenville. An army reserve colonial division arrived in the night to form the connecting link between the II. Corps and the XII. The XVII. Corps also had let itself be surprised, so that the XII. Corps, flanked on the right by the Colonials and on the left by the XVII. Corps, was in a critical position. Farther westward, the XI. Corps attacked Offagne without success, and the IX. gained ground on the left, being kept informed by the cavalry corps. In sum, there were tactical reverses nearly everywhere; nevertheless, the general commanding gave orders to resume the attack next day (Aug. 23).

It was now a recognized fact that, contrary to Joffre's belief, there was no gap in the Ardennes; the Duke of Württemberg's corps were being identified one by one, as well as those of the Crown Prince's right wing; and, near the extreme left, the IV. Army was in touch with cavalry of the German III. Army.

On Aug. 22 the French III. Army had given way badly in the centre and on the right; and the IV. Army had lost its offensive power. On Aug. 23 the attacks contemplated had to be given up and a retreat was made, during which the XII. Corps suffered a severe reverse.

Meanwhile the I. Army at Sarrebourg, the II. at Morhange, the V. at Charleroi, suffered tactical reverses at least as great as those experienced by the III. and IV. Armies, between Longwy and Dinant. The tactical instruction of the French army, badly given owing to a lack of training camps, and for various other reasons, was the real cause of the reverses at the beginning of the campaign. If, in addition to this, one notes the splendid conduct of the I. Corps of the V. Army, the II. Corps of the IV. Army, the VI. Corps of the III. Army, the XX. Corps of the II. Army; if, in contrast, it is stated that at Dinant the Boutegourd Res. Div. was seized by panic and announced the presence of a German army whereas there was only some cavalry supported by a few infantrymen; that to the left of the IV. Army two reserve divisions were doing nothing, and to the right of the III. Army were others which were of no help to the 40th Active Div., one begins to realize that the frontier army corps, which included hardly any reservists, the I., II., VI., and XX., were splendid; that the army corps stationed in the interior had much to learn and were receiving hard lessons; finally, that the reserve divisions were as yet useless. An army requires an acclimatization more or less long in proportion as it contains inexperienced and older men. A still more important deduction may be made: since the lesson was needed to teach the French army the same lesson would have resulted in defeat anywhere else. The French army was bound to lose the first battle, whether it took place in plain or forest, in the offensive or in the defensive. Joffre's strategy could not make up for the tactical insufficiency of Joffre's army. The German armies beyond the Moselle and the Meuse were effecting their strategic deployment. The first ready were to wait for the entire completion of the plan established by the Berlin staff. A battle accepted before all the armies were placed would be a strategic reverse. The much-criticised French offensive inflicted this reverse upon German strategy. The German III. Army was not at the battle; the German I. Army only arrived after Lanrezac had escaped, and although the English army was in great danger, on Aug. 23, it was nevertheless able to avoid the destruction reckoned on by the enemy. The German V. and IV. Armies, obliged to wait until the deployment of the *ensemble* was completed, merely engaged a defensive battle, to which, it is true, fierce counter-attacks were added; but the counter-offensive which the Crown Prince of Germany and the Duke of Württemberg ought to have led, and which might have had incalculable consequences, was not forthcoming.

Joffre, Ruffey, de Langle de Cary, had a powerful influence over their subordinates. There were blunders of appreciation on their part in this "battle of the two blind men," but a determination to manœuvre. This determination to manœuvre was to be found again at the Marne, and this time Joffre's eyes were opened. The German commanders kept to their book knowledge, merely carrying out what was written; they allowed their troops to act, their troops, not they, won the battle. The lesson of Charleroi instructed the French army; time, and subsequent battles, accustomed the active and reserve units to war. At the Marne German tactical superiority existed no longer; Joffre's strategy defeated the strategy of the German Supreme Command.

The French general-in-chief was still blind on the morning of Aug. 23; during that day he received the reports; on the evening of Aug. 24 "the veil was torn"; he saw his strategic mistakes, saw into the enemy's game, and understood the causes of most of the tactical reverses met with. He determined to carry the centre of gravity of his forces westwards; to recall to the minds of all that the true French fighting doctrine is based on protection and the coöperation of arms; to take their command from those chiefs who gave way. These were the results of the battle of the Ardennes, results unfortunately obtained at far too high a price. The Germans learnt nothing at the battle of the Ardennes. Their self-confidence was increased. At the battle of the Ardennes, we may say, there were two blind men; at the battle of the Marne, Joffre had been operated on for cataract, while the Kaiser had allowed the film on his eyes to grow thicker.

*Battle of the Meuse.*—By the evening of Aug. 23 1914 the intention of the French general-in-chief had not met with success at any point. Gen. Ruffey showed a desire to take up the

offensive, but his troops were unfit for it. The III. Army, while retreating, had turned round the left of the IV. Corps. The latter was firmly supported by the right of the II. Army Corps, which had not given way. The point of touch between the armies was at Mont-Quintin, to the N.E. of Montmédy. The V. Corps needed to recover its strength and the 40th Div. of the VI. Corps was in a bad condition after its efforts of the previous day. The Colonial Div., which had formed Gen. de Langle de Cary's army reserve, had been pushed on by him to the first line, and was ordered to resume the attack by pivoting round the II. Corps, which was to wait until the Ruffey army was enabled by an advance northward to cover its right flank. But the IV. Army was not in a condition to attack; on the left the J. B. Dumas Div. of the IX. Corps, which was fresh, pushed forward, but found itself in a difficult position, since on its right the XI. Corps remained in the rear. During that day the XII. Corps, both its flanks uncovered owing to its neighbours having given way, had a serious check.

Generally speaking, on the evening of the 23rd, the front of the IV. Army was marked by a straight line drawn from Monthermé to Mont-Quintin, near Virton, and facing north-eastwards; the front of the III. Army, by a straight line extending from Mont-Quintin to Nouillon-Pont-Spincourt through Marville. Gen. de Langle de Cary was ready to make any sacrifice to prevent the right flank of the V. Army from being uncovered; Gen. Lanrezac, on the other hand, had retreated on his own authority and without warning his neighbours.

On the 24th the IV. Army was astride the Meuse, its front being marked by Revin, Mézières, Donchery, Douzy, St. Walfroy and Avioth; at Mont-Quintin it was in touch with the III. Army. There was some fighting during the day in different parts of the front of the IV. Army. On the left wing, the IX. Corps, which had been joined by the Moroccan Div., moved from the Semoy to Mézières without being followed by an enemy on whom it had inflicted a severe lesson. On the morning of the 25th the II. Army Corps sent patrols from Avioth to Lahagne, near Bellefontaine, to bring back wounded men who had been left there because unfit to be moved. One of the patrols (Lt. Benoît, of the 18th Chasseur Battalion) killed a German staff commander on whom were found the orders given to the German IV. Army for the forcing of the Chiers and Meuse crossings, on Aug. 26 and 27.

In the IV. Army, a patrol (Sergt. Ronchon of the 3rd Hussars) attacked a German motor-car and seized orders which showed that the German 33rd Res. Div. was to attack from Metz towards Etain. A trap was set for that division, not without great difficulty, owing to the lack of coördination between the staffs of the III. Army, the Lorraine army, and that of the general-in-chief. All the energy of Col. Tanant, staff sub-chief of the III. Army, was required to organize a manœuvre. If, however, the German 33rd Res. Div. managed to escape on account of these difficulties and because the reserve troops were slow to move, they did not do so without confusion and considerable losses. Thus, the French IV. and III. Armies had not lost all material and moral value, as was believed in the German camp. As soon as the ground was in their favour they would be able to resist the enemy.

During Aug. 24 the Colonial Corps had had to repulse violent attacks at St. Walfroy, and the V. Army Corps had beaten a somewhat hasty retreat. On the 25th the right of the IV. Army retired between Chiers and Meuse; the same day the IV. Corps experienced so serious a check at Marville that its chief, Gen. Baille, who was in close touch with Gen. Gérard, asked him to undertake to bring back his corps artillery regiment to him. This detail shows how intimate was the coöperation between the III. and IV. Armies.

The right of the III. Army, badly covered by the cavalry division, whose chief was, moreover, relieved of his command, was left in the air by the suppression of the Lorraine army (night of Aug. 25–26). Gen. Maunoury, indeed, received orders to leave the defence of the Hauts-de-Meuse to Gen. Pol Durand and to return their respective forces to Verdun and Toul. Gen. Maunoury himself, with his staff, with Gen. Beaudenom de Lamaze and the 55th and 56th Res. Divs., was to proceed to Montdidier. It is well known that this was how the VI. Army was formed; their attack on the Ourcq, in concert with the English army and the French V. Army, brought about the rout of the German right at the Marne.

In the morning of Aug. 26 the right of the IV. Army and the III. Army crossed to the left bank of the Meuse. Dun (IV. Corps) was the point of junction between the IV. and III. Armies on the morning of the 26th. By the evening of that day the III. Army was almost entirely on the left bank of the Meuse, facing eastwards; the IV. Corps to the N., the W. and the S. of Dun; the V. Corps in the Montfaucon region, the VI. Corps to the S. of Montfaucon and the N. of Verdun (H.Q. at Esnes). The 7th Cav. Div. was sent to Dombasle, between Verdun and Clermont, as though the army commander feared the enemy might turn Verdun by the S. and take the III. Army in reverse. The 42nd Div. had remained as an advanced guard on the right bank of the Meuse; on the afternoon of Aug. 27 it received orders to cross to the left bank; on the 28th it passed into the army reserve at Varennes. This division was, moreover, to be taken from the VI. Corps and allotted to the army detachment under the command of Gen. Foch.

The III. Army did not come in contact with the enemy on the 26th and 27th. But the 7th Inf. Div. was summoned towards Beauclair, to the W. of Stenay, and placed at the disposal of the II. Corps, while the front of the 8th Div. was extended nearly as far as the road from Stenay to Beauclair. Thus the German V. Army was not in pursuit; it was slowly advancing towards the Meuse, its left at Ornes alarming the governor of Verdun who asked the IV. Army for assistance. The centre passed through Damvillers; the right caused uneasiness towards Stenay.

On the evening of the 25th the orders to the IV. Army ran: "To-morrow the IV. Army will establish itself on the left bank of the Meuse in order to resist." On the evening of the 26th the orders were as follows: "From to-morrow the IV. Army will engage the decisive battle on the Meuse." These last instructions were enthusiastically received by the troops. The II. Corps was to defend the left bank of the Meuse, from Stenay to Luzy. The Colonial Corps, on its left, was to defend the crossing in the neighbourhood of Inor, leaving one division as an army reserve at Vaux-en-Dieulet. The XII. Corps was to hold the crossings of the Meuse in the Joncq region, the XVII. Corps facing Mouzon. The XII. Corps, reënforced by the 52nd and 60th Res. Divs., was to prevent the crossing of the Meuse between Remilly and Mézières. By the evening of Aug. 24 the 4th Cav. Div. had been given back to the V. Army. The mission of the 9th Cav. Div. (Gen. de l'Espée) was to ensure the communications, in conjunction with the IX. Corps.

On the evening of Aug. 25 the IX. Army Corps (Gen. Dubois) received the special mission of covering the Signy-l'Abbaye region and forming the connexion between the IV. and V. Armies. The situation, indeed, was becoming serious on the left of the IV. Army. The Saxon III. Army, of whose existence the French army had long remained ignorant, had shown signs of its presence since the 24th. The French V. Army, thanks to its retreat, no longer risked being taken in reverse; but as a large space unoccupied by troops existed between the IV. and V. Armies, it was to be feared that the German III. Army might penetrate there in order to act against the wing of one or other of the two French armies, according to its inclination. Gen. Dubois found himself thrust into the space, with the 9th Cav. Div. to assist him. His position was unique all through the campaign, and it was owing to the suppleness of his manœuvring that Gen. Dubois succeeded in performing the difficult mission with which he had been entrusted. On the evening of Aug. 25, he placed one of his divisions at Renwez (10 km. N.W. of Mézières), facing the Meuse and the N1; and the other division farther eastward towards Rocroi in the N. and Signy-l'Abbaye in the south. He thus completely covered the left flank of the IV. Army.

FRONTIERS, BATTLES OF
THE (CHARLEROI)

PLATE IV.

At the very moment when Gen. de Langle de Cary gave orders to engage the decisive battle on the Meuse (Aug. 26, 2 P.M.), the right of the German IV. Army forced the crossing of the Meuse at Donchery; the French V. Army had given ground on the Serre, thus completely uncovering the left of the French IV. Army, and important enemy forces were reported in the Rocroi region (von Hausen army).

The commander of the IV. Army ordered Gen. Dubois to proceed, on the 27th, to the Signy-l'Abbaye-Launois region in order to cover the left flank of the IV. Army.

Already by the morning of the 27th, as the fog lifted, the Germans, who had been allowed to cross the Meuse freely between Stenay and Inor, passed to the attack. Gen. Gérard had given orders to throw back into the Meuse all enemies who sought to debouch therefrom. A division of the German VI. Corps was therefore allowed to emerge from Luzy and Cesse; then, after being taken under the fire of the batteries, it was counter-attacked by a Colonial regiment and two rifle battalions and thrown into the Meuse. In this part of the battlefield the Germans experienced nothing but reverses, their attacks being always badly supported by their artillery, which contented itself with throwing large projectiles at random.

The Colonial Corps engaged fierce battles with the German troops that had crossed the Meuse at Pouilly; Gen. Leblois' division was beginning to retreat when the arrival of reserves from the II. Corps reëstablished his position. The XII. Corps, weakened by the losses sustained during the previous engagements, seemed, at one moment, to have imperilled its situation; it managed nevertheless to maintain its position. The XVII. Corps had deprived itself of one of its divisions, according to the orders of the commander of the IV. Army, to relieve the XI. Corps. It now comprised only the 33rd Div., some of the artillery of which had been lost at the battle of the Ardennes; fortunately the whole German effort was directed to the battle of La Marfée, and the XVII. Corps was able to remain on its positions.

The XI. Corps, established on the evening of the 25th in the woods of La Marfée, was attacked there early on the 26th by the enemy forces which had crossed the Meuse at Donchery on the one hand and at Remilly on the other. After fighting all day the XI. Corps and the 60th Res. Div. were obliged to retire somewhat. On the same day, the 52nd Res. Div., threatened by the XII. Saxon Corps on its left, concentrated to the W. of Mézières and took up its positions between the 60th Div. and the IX. Corps. On the 27th the fighting continued. The enemy, surprised in dense masses, was crushed by the 75-mm. guns and thrown back in disorder on Noyers, leaving the flag of the 68th Prussian Regt. (VIII. Corps, 16th Div.) in the hands of the 137th French Infantry. On the right, then, the XI. Corps won a great success; but on the left, the battle long remained doubtful. In the evening an imprudent move, similar to that of Noyers, was made by the Germans at La Marfée, and after heavy losses they were driven back towards the Meuse. On the same day, under a slight pressure from the enemy, the IX. Corps and the 52nd Res. Div. came and occupied the positions fixed by the orders.

The French IV. Army considered itself victorious, and Gen. de Langle sought leave from H.Q. to continue the battle and take the offensive. "We see no objection," was the answer; "to your keeping your positions to-morrow, Aug. 28, in order to assert our success and to prove that our falling back is merely strategic; but on Aug. 29 everybody must be in retreat."

On the evening of Aug. 25 the German III. Army was in the region of Fumay; on the 26th in the neighbourhood of Rocroi; during the night of the 27th–28th it came in touch by its right with the IX. Corps in the Signy-l'Abbaye region, and, by its left with Mézières, in touch with the IV. Army. The VIII. Corps and the VII. Res. Corps of the German IV. Army were fighting S. of Donchery and Sedan. More to the left the XVIII. Corps had crossed the Meuse at Remilly, the XVIII. Res. at Mouzon, and the VI. Corps at Luzy-Cesse, in touch with the V. Army.

On the 28th nothing took place between Stenay and Inor; there was some slight action near Jonon, but with no result. In the XII. French Corps there was some hesitation; in the XVII. Corps nothing of importance took place, except a few falsely interpreted orders which made void some slightly successful results.

In the XI. Corps the successes of the previous day were continued. At about 6 P.M. a finely conducted charge drove the enemy from all the positions they had previously conquered and for which they had paid heavily. But evening was drawing near and, in order to conform with the orders of the general-in-chief, though much to their distress, Gen. de Langle de Cary and his troops were obliged to retire.

The battle of the Meuse was ended; and Gen. de Langle, in general order No. 27, on the evening of Aug. 28, said: "The Army inflicted heavy losses upon the enemy, yesterday and to-day. It returns to the Aisne line, in accordance with orders received, to prepare for the offensive in a new direction."

While the IV. Army was fighting, the III. Army remained practically inactive opposite the German V. Army, which showed no particular dash.

*Battles of Signy-l'Abbaye.*—On the left of the French IV. Army Gen. Dubois was fighting on the same day (Aug. 28) at Signy-l'Abbaye against troops as numerous as they were badly commanded. A German Army (XII. Active Corps, XII. Res. Corps and XIX. Active Corps), of which the French staff knew only the XII. Active Corps, was advancing towards Rethel, in the gap between the IV. and V. Armies. On the 28th, at 3 A.M., the outposts of the Moroccan Div. (Gen. Humbert) were attacked; the Zouave Regt., threatened with envelopment, escaped towards the S.E., after three hours' fighting, leaving the road to Signy-l'Abbaye open to the enemy, who entered, at 11 A.M., after a slight engagement. This German advance to the S., towards Rethel, threatened the communications between the IX. Corps and the troops in the rear, and cut off those between the French IV. and V. Armies. Gen. Dubois then gave the Humbert Div., which was very flexibly quartered in the region N. of Launois (6 km. S.E. of Signy-l'Abbaye), orders to attack Signy-l'Abbaye. A fierce battle was engaged midway, at Dommery, which was taken, lost and retaken. The fighting front spread northward, both sides being reënforced. At nightfall nothing was decided, but the enemy's advance to the S. was checked. The commander of the 17th Div. (J. B. Dumas) could hear the guns from La Marfée, and claimed leave to hasten in that direction. The 9th Cav. Div. gave the support of its guns to the Moroccan Div., but would have done better to interpose between Signy-l'Abbaye and Rethel. A French infantry and *cuirassier* detachment took up position at Novion-Pornin, thus cutting off the road to Rethel. But although the enemy were unable to enter Novion-Pornin they remained in touch, and the following morning entered the town without resistance, its defenders having withdrawn to join their respective corps. Thus, on the morning of the 29th, the road to Rethel was in the hands of the enemy; the IV. Army was retreating; the IX. Corps was still under orders to cover the left of the IV. Army and to remain in touch with the V. Army. But the enemy had now interposed between the IX. Corps and the V. Army. The commander of the IV. Army, who was not yet informed of the battle of Signy-l'Abbaye, gave orders, on the evening of Aug. 28, to maintain the positions: in the Poix-Terron region on the 29th, and before Rethel on the 30th. Gen. Dubois decided to interpose between Signy-l'Abbaye and Rethel. He sent the 9th Cav. Div. to the S. of the forest of Signy; gave orders to the J. B. Dumas Div. to advance on and capture Novion-Pornin; to the Moroccan Div. to act as a screen in front of the J. B. Dumas Div. while this movement from the N.E. to the S.W. was being effected, then to stop the fighting and take up position E. of that division.

By the evening, not without fighting or without difficulty, and in spite of a whole German Army to oppose the proposed manœuvre, Gen. Dubois was in front of Rethel, at the spot where the situation made his presence necessary. On the same day he was to pass under the command of Gen. Foch, commander of an army in formation, the IX. Army. The French army, on

the evening of Aug. 29, was no longer the French army of Aug. 22; it was soon to become the army of the Marne. (V.L.E.C.)

### (4.) Battle of Charleroi

On Aug. 21, 22, and 23 1914 the French V. Army fought the battle of Charleroi, E. and W. of that place, in the angle formed by the rivers Sambre and Meuse.

By Aug. 20 1914 the forward movement of the German right-wing armies into Belgium, and the failure of the offensive of the French I. and II. Armies, had caused a modification in Gen. Joffre's original plan of campaign; and the plan of operations, after being adapted each day to the general situation, finally took a definitely new shape. Broadly speaking the intention now was to make the principal attack through Luxemburg and Belgian Luxemburg with the object of threatening the communications of such German forces as had crossed the Meuse between Namur and the Dutch frontier. This duty devolved primarily on the III. and IV. Armies of the French. In the S. the I. and II. Armies were to make a secondary offensive between Metz and the Vosges to hold the enemy, who might otherwise be able to take in flank the French advancing through Luxemburg; and the French V. Army and the British army were to act upon the offensive, though this offensive would depend almost entirely on success by the III. and IV. Armies to their right. The offensive of those armies, however, collapsed, and this had an immediate effect upon the French V. and British Armies in the zone Charleroi–Mons, for they were then left in an isolated state some 40 m. to the N. of the remainder of the French battle-front. It has been said that "the battle of Charleroi was lost before it was fought"; and though this statement may be demurred to, the peculiar situation of the V. Army must be borne in mind in studying the battle.

On the evening of Aug. 20 1914 the situation of the V. Army was as follows: Of the I. Corps (reënforced by the 8th Infantry Brigade) the main body was W. of Dinant, with detachments on the Meuse from Revin to Namur, and on the Sambre from Namur to Floreffe; the 51st Reserve Div. attached to the corps was about Rocroi en route for Dinant. The X. Corps (reënforced by the 37th Div.) had its main body in the area Fosses–Philippeville, with detachments along the Sambre from Ham to Tamines. The III. Corps (reënforced by the 38th Div.) had its main body in the area Gerpinnes–Joumioux–Gourdinnes, with detachments on the Sambre from Rosalies to Marchiennes. The cavalry corps of Gen. Sordet was behind the Brussels–Charleroi canal, with detachments holding the passages from Gosselies to Seneffe. The head of the XVIII. Corps—which had been transferred from the II. Army—had reached Beaumont in its march to Thuin. The 53rd and 69th Reserve Divs. of Gen. Valabregue were in the area Vervins–Hirson. Army headquarters were at Signy-le-Petit. The V. Army was commanded by Gen. Charles Louis Lanrezac, an officer with an extremely high reputation in France. On April 10 1914 he had been made a member of the Conseil Supérieur de la Guerre.

Throughout the 20th the French cavalry had been in contact with that of the Germans. North of the Sambre this contact had been gained by the cavalry of the I., X. and III. Corps, while the cavalry corps of Gen. Sordet was in touch with German mounted troops on the line Charleroi–Nivelles. It was on this day that there arrived from G.H.Q. the orders for Gen. Joffre's new offensive. The orders were to the effect that all information pointed to the intention of the Germans to carry out an outflanking movement in the north. The French III. and IV. Armies had been ordered to march against the line Neufchâteau–Arlon. As for the V. Army, its task was to pivot on Namur and the Meuse, and to seek out the main enemy mass in the north. On the left of the V. Army the British army would advance towards Soignies in the direction of Nivelles.

Gen. Lanrezac considered that it was not possible to carry out the order, so far as it affected his V. Army, at once. To begin with, the I. Corps, to be made available, must await relief by the 51st Reserve Div., marching up from Rocroi to Dinant, and this relief could not be effected until the evening of the 22nd. The XVIII. Corps on the left might, it is true, be up by the afternoon of the 21st; but even with this reënforcement Gen. Lanrezac considered it imperative to wait until the I. Corps—his best troops—should be available. Then it had to be borne in mind that the British had not yet come up on the left, and that the action of the V. Army would also depend upon the success of the French IV. Army on the right. Gen. Lanrezac therefore confined himself for the moment, while awaiting the opportunity of assuming the offensive, to issuing orders for the occupation of a defensive position by the X. and III. Corps S. of the Sambre.

On the side of the Germans a combined attack had been arranged in which the II. and III. Armies were simultaneously to attack the French V. Army, from the N. and E. respectively. This operation had been ordered on Aug. 20 by Supreme Headquarters, who had directed that the I. and II. Armies were to close up to the line reached on that day, and that an offensive against the enemy W. of Namur was to be carried out in coöperation with an attack by the III. Army against the line of the Meuse between Meuse and Givet, details being left for decision by the Army headquarters concerned. It was stated that at least three French corps were between Namur and Givet, and that more enemy columns were advancing northwards between Namur and Maubeuge. As regards the British the German Intelligence Department was woefully at fault, for it was stated that "a disembarkation of the British forces at Boulogne and the neighbourhood must be taken into account. It is the opinion here, however, that a landing on a large scale has not yet taken place." At the time two-thirds of the British force was within 30 m. of Gen. von Bülow—a striking testimony to the celerity and secrecy with which the transport of the British army to the continent had been accomplished.

During the day the Germans attacked the French detachments on the Sambre. Tamines and Rosalies were taken, and early in the afternoon some of the Prussian Guards crossed the river at Auvelais and held it against French counter-attacks. Farther W. the cavalry of Gen. Sordet was also attacked about half-past three in the afternoon, and it was found necessary to send an infantry brigade to its support. Thus Charleroi was threatened from both E. and W., and during the night shells fell upon the railway station in the town. The events of the day had resulted in dislocating Gen. Lanrezac's preparations for the offensive, and at 12:30 P.M. he wrote to Gen. Joffre as follows: "I consider it dangerous to let the V. Army cross the Sambre during the 22nd minus on the one hand the I. Corps, which must hold the Meuse until the IV. Army has made sufficient progress N. of Semoy, and minus on the other hand the English who on the 22nd will not be able to get farther than Mons." During the evening a reply came from Gen. Joffre to say that Gen. Lanrezac could choose his own time for the offensive, and he accordingly decided that it would be launched on the 23rd.

Early on the 22nd fighting was resumed all along the French front on the Sambre. The X. Corps was forced back, and during the afternoon the road from Fosse to St. Gerard was crowded with artillery, infantry and transport moving southward, which was probably the disquieting incident witnessed by Sir John French in his visit to the zone of the V. Army on this day. Fosse was occupied by the Germans about 8 P.M. Farther W. the III. Corps had likewise to give ground. Severe fighting took place early in the afternoon round Chatelet, and both divisions had to retire, the 5th towards Tarcienne and the 6th to Nalinnes. By one o'clock the III. Corps had definitely to renounce its grip on the southern outskirts of Charleroi. The city had witnessed fighting of extraordinary severity, and according to some accounts it was lost and won five times before the Germans were permanently masters of it. In the narrow streets between the Sambre and the canal the carnage was almost indescribable, and in places the dead and wounded blocked the way to those who were still unscathed. Here and there the bodies of the slain formed ramparts from which sharp-shooters kept up a murderous fire; and the Germans as they pressed on marched on a veritable *chaussée* of corpses. A

French survivor has left on record a vivid description of the scene in the town. "In the narrow streets the Germans pushed on in close order, and the French guns made such havoc in their ranks that the air was full of flying arms and heads and legs, of boots and helmets and swords and guns, that it did not seem to be real—it looked like some burlesque. Even one of the gunners turned sick at the sight and turned to his commander saying, 'For the love of God, Colonel, shall I go on?' And the Colonel, with folded arms, replied, 'Fire away.'"

As for the XVIII. Corps, it came upon the field, but was S. of the Sambre between Thuin and Malines instead of being, as Gen. Lanrezac had hoped, on the Mons–Charleroi road in touch with the British. The Cavalry Corps of Gen. Sordet had fallen back during the night to Solre, and in the afternoon was sent to guard the crossings from Jeumont to Thuin, and also to hold the cross-roads at Merbes Ste. Marie on the far side of the river. The night march following on long and arduous work in Belgium had been fatiguing to the horses, and the cavalry corps was in need of rest. Gen. Joffre had prescribed that it was to move to the British left, but Gen. Lanrezac considered that it was not in a fit state to move until the evening of the 23rd. It was not, however, until the 26th that it arrived on the outer flank of the British in the battle of Le Cateau.

To Gen. Lanrezac on the evening of the 22nd the situation of the V. Army seemed grave, but by no means desperate. Only two of his corps, the X. and III., had been engaged, and if these had suffered heavily they had also made the enemy pay the price. Withdrawn to more open terrain, where their artillery could render better support, they could re-form and, so he hoped, in their turn take the offensive. Further, the I. Corps was intact and now becoming available on the right, as was also the case with the XVIII. Corps on the other flank; and the reserve divisions of Gen. Valabregue were coming up to support it. And as for the British, they were now arriving in position on the left round Mons. In one way Gen. Lanrezac was much more fortunate than he knew. Gen. von Bülow had attacked prematurely by forcing the Sambre on the 22nd instead of waiting for the attack of the III. Army against the Namur–Givet section of the Meuse to take effect, and the retirement of the V. Army during the 22nd had seriously discounted the German chances of enveloping it.

The chief interest in the battle of Charleroi is bound up with the narrative of the operations of Aug. 23, the day on which the British forces were engaged in the battle of Mons on the left of Gen. Lanrezac's army. Particulars of the battle were long shrouded in mystery, and the phrase *"L'énigme de Charleroi"* even came into current use.

On the morning of Aug. 23 the situation of the French V. Army was as follows: The I. Corps had one division echelonned from Sart St. Laurent to Lesves; the main body were assembling in the area Ermerton-sur-Biert–Anthée; three battalions were detached to Namur; the 51st Reserve Div. was holding the Meuse from Hermeton to Yvoir; all bridges had been destroyed except those at Dinant and Hastière. The X. Corps had its right on the high ground S. of Fosse and Vitrivel, left at Scry. The III. Corps (reënforced by a brigade from the XVIII. Corps) was deployed on the line Gerpinnes–Nalines–Claquedent. The XVIII. Corps was on the line Ham-sur-Heure–Thuin, with detachments on the Sambre as far as Merbes-le-Château. The cavalry corps of Gen. Sordet was holding the passages of the Sambre from the left of the XVIII. Corps to Maubeuge. The 53rd and 60th Reserve Divs. (Gen. Valabregue) were about Solre le Château.

Gen. Lanrezac's orders were to the effect that the X., III., and XVIII. Corps should hold on to their positions; the I. Corps should form up on the right of the X., and, if possible, act against the left flank of the Germans attacking the corps. The reserve divisions of Gen. Valabregue were to relieve the cavalry corps of Gen. Sordet, which was to make for Maubeuge with the object of emerging eventually on the left flank of the British army.

On the German side the orders of Gen. von Bülow were briefly as follows:—The attack was to be continued on the 23rd on the following frontages: the VII. Corps, left of the line Thuin–Boussu–Cerfontaine, was to cover the right of the II. Army from Maubeuge and to reconnoitre in the direction of Avesnes; the X. Reserve Corps was to attack E. of the line Charleroi–Philippeville; the X. Corps was to attack E. of line Tamines–Mette-Rosee; the Guard Corps was to attack on the left of the X.; the line Fontaine–Valmont–Mettet was to be crossed at 8 A.M.

In his published account of the battle Gen. Lanrezac divides it into two distinct phases, the first from daybreak until 4 P.M., and the second from that hour until nightfall. In the first phase the course of the battle was as follows: The right wing of the X. Corps was driven back, and it re-formed between Scry and St. Gerard; the I. Corps deployed on the high ground round St. Gerard with its right about Sart-St. Laurent. This operation was completed about midday, and the I. Corps was then well placed to act against the flank of the Guard Corps, which was then attacking the X. Corps sharply. Gen. Franchet d'Espérey, commanding the I. Corps, instantly resolved to seize the opportunity and to attack *au fond*. His artillery prepared the way by an intense fire, and the Germans, apparently taken by surprise, suspended their attack to deal with this new danger. It was now about one o'clock, and Gen. Franchet d'Espérey was about to launch his infantry when disquieting news reached him from his right rear. The 51st Reserve Div., which had relieved the I. Corps on the Meuse, had failed in its task, and had allowed troops of the German III. Army to cross the river. The report went on to say that the reserve battalions had fallen back in disorder and that a detachment of the enemy had occupied Onhaye behind the V. Army. Gen. Franchet d'Espérey had no alternative but to suspend his attack and to send a division and a brigade to deal with the peril behind. Emboldened by the enforced inaction of the French the Guard Corps again pressed on, its artillery maintaining a very severe fire. The French X. Corps and the fraction left of the I. Corps resisted energetically, with the result that in this portion of the field but little ground was lost, and connexion was still maintained with the fortress of Namur.

While such was the state of affairs on the right wing, little was, in this first phase, taking place on the left wing. But after four o'clock a change for the worse set in in that portion of the field. The left wing of the III. Corps was taken by surprise and driven back by a sharp attack, with the result that the whole III. Corps fell back in confusion to the line Chastres–Morialme, while the XVIII. Corps, with its right now uncovered by the retirement of the III. Corps, was forced to withdraw to the stream which runs from Thuilles to Thuin. The reserve divisions of Gen. Valabregue, however, had come up to Bousignies and Thirimont. On the right wing, in this second phase of the battle, the X. Corps had been forced to admit a loss of ground, but it was only slight, and when night fell the corps was holding the line Graux–Mettet–Wagnée. As for the I. Corps the portion left at St. Gerard was holding its ground.

Reference has been made to the danger which was threatening the right rear of the V. Army by a German advance across the Meuse. The attack in this quarter was being carried out by the German III. Army in which the XII. Corps had been ordered to force the passage of the river at Houx and Dinant. To the right the XII. Reserve Corps had been directed to seize Yvoir, while on the left the XIX. Corps was ascending the river on the right bank towards Givet and Fumay.

During the 23rd, as already related, Gen. Franchet d'Espérey had been called upon to deal with the presence of a detachment of the III. Army which had forced its way over the river. A brigade was directed upon Anthée, and to it was attached the provisional cavalry brigade from the X. Corps. On arrival at Anthée, about 6 P.M., the cavalry proceeded to reconnoitre in the direction of Dinant, as well as the villages of Onhaye and Leuze. Some sharp fighting took place, and about 10 P.M. the French infantry carried Onhaye with the bayonet. It appears that this attack by the French came upon the Germans somewhat by surprise, and the units of the III. on the right bank of the Meuse were in consequence retained there for the moment.

In addition to the above-mentioned French detachment the 2nd Div. had been sent from the I. Corps. That division moved upon Morville but was not engaged.

At the end of Aug. 23 Gen. Lanrezac weighed in his mind the various happenings of the day, and quickly came to the conclusion that immediate retreat was called for on the part of the V. Army. The chief causes of his decision are given by himself as follows: In the first place he had learnt definitely that the offensive of the IV. Army had failed and that the beaten troops were falling back to the Meuse with the left of the army on Mézières. The line of the river between that place and Givet was guarded by but a few battalions of reserve troops, whose efficiency Gen. Lanrezac had reason to suspect. The rear of the V. Army was thus threatened once again. In the second place Namur had fallen, and this incident undoubtedly made a profound difference to the strategic situation; in addition the roads on the right flank of the V. Army, already encumbered with thousands of civilian refugees, would be further blocked by the retreating Belgian troops from the fortress. Thirdly, the British army was checked, and *l'on peut prévoir qu'elle va être obligée de retrograder*. It is perhaps a sufficient refutation to this statement to say that half the British army had not been engaged at all, that the other half had held off the Germans without serious difficulty, that the total British losses were less than 2,000, while a moderate estimate of the casualties inflicted on the Germans would be more than twice that number, and that when night fell the universal opinion among the British rank and file was that they had won a victory. Gen. Lanrezac, however, issued orders for the V. Army to retire on the 24th to the line Givet–Philippeville–Beaumont–Maubeuge. Amongst the officers of his own staff the decision does not seem to have been well received; and Gen. Lanrezac relates that "*quelques officiers de mon état-major loin de reconnaître ma clairvoyance me taxent de pusillanimité; pour eux je ne suis 'qu'un catastrophard' dont il faut se debarrasser au plus vite.*"

On the 24th the retreat began before daybreak, and the line Givet–Maubeuge was reached without incident other than the action of rear guards, who easily held off the advanced guards of the German II. Army. The right flank was covered by the 2nd Div. of the I. Corps, which fell back slowly from position to position without any interference by the enemy, and at nightfall it bivouacked immediately N.W. of Givet. (F. E. W.*)

### (5.) Mons and Le Cateau

The battles of Mons and Le Cateau were fought by the British on Aug. 23 and 26 1914 respectively, against the extreme right wing of the Germans during the advance of the latter through Belgium and northern France.

When England declared war on Germany during the night of Aug. 4–5 her forces available to take the field consisted of a cavalry division, six infantry divisions, and some battalions of line-of-communication troops, the whole forming the Expeditionary Force for service overseas. The Government decided to retain two divisions temporarily in the United Kingdom and to transport the rest of the Expeditionary Force to France. The first ships sailed on Aug. 9, and, thanks to the perfection of the arrangements for mobilization and transportation, the operation was completed without a hitch by Aug. 18. Sir John French, the British commander-in-chief, had reached his headquarters at Le Cateau on the previous day; and his army consisted of the I. Corps (1st and 2nd Divs.), Lt.-Gen. Sir Douglas Haig; II. Corps (3rd and 5th Divs.), Lt.-Gen. Sir Horace Smith-Dorrien; and the cavalry division under Maj.-Gen. Allenby. Concentration was completed by the 20th S. of Maubeuge, and the post assigned to the British was on the left of the French V. Army, preparatory to an advance N. of the Sambre towards Soignies.

The two following days were spent in moving forward to positions about Mons which were reached on the 22nd; and on Aug. 23 the position of the Allied forces in the N.W. of France was as follows: From Valenciennes by Lille to Dunkirk were some French territorial divisions, of which one, the 84th, was at Condé. Working from left to right, then came along the canal the British 19th Bde., made up of battalions of line-of-communication troops. Then came the 5th Div., while next on the right was the 3rd Div., holding a salient round Mons as far S.E. as Villers St. Ghislain. The line was continued by the British I. Corps farther south-eastwards to Peissant. The cavalry division was in rear of the British left, except the 5th Cav. Bde., which was posted in advance of the right flank. The French V. Army, farther to the right, was now in rear of the line held by the British.

The British position was thus in shape somewhat that of a broad arrow, with the two army corps practically at right angles to one another and facing, generally speaking, E. and N. respectively. As matters turned out the German attack was directed almost entirely against the II. Corps, and here on the left the situation was favourable to the British, for the canal made a valuable defensive line, while the terrain on the farther side held numerous difficulties for the attackers. Muddy ditches and barbed-wire fences impeded their movement, although on the other hand groups of trees and bushes gave useful cover from view and were of service for the enemy's machine-guns. South of the canal the crests of the high ground afforded the British useful sites for artillery, but the slag heaps of the numerous mines limited observation to some extent. The line of the canal, however, had one very disadvantageous feature: after running from Condé to Mons in a mathematically straight line, it forms a loop round Mons, thus constituting a marked salient. Such a position might easily be found to be untenable, and Sir Horace Smith-Dorrien had prepared another and more defensible line in rear running through Frameries–Paturages–Wasmes–Boussu. During the 22nd Sir John French had visited the area of the French V. Army on his right, and had been somewhat disconcerted to meet columns of infantry and artillery moving south. As the left of the V. Army, formed by some reserve divisions, was drawn back, and the centre and right were in process of retiring, Sir John French considered that his own position on the Mons canal might quickly become very precarious. He accordingly informed Gen. Lanrezac that he would hold his position for 24 hours, but that the retirement of the V. Army might require a withdrawal of the British, after that time, to the Maubeuge position.

On the German side the battle of Charleroi (*see* above) was not producing all the effect hoped for by the Germans. The German plan had been that the II. Army was to attack S. across the Sambre, while the III. Army was to coöperate by attacking W. across the Meuse, towards Mettet, sending a strong force across the Meuse by Dinant towards Rocroi to bar the French line of retreat. As for the extreme right army of the Germans (the I. under Gen. von Kluck, who was temporarily subordinated to Gen. von Bülow) during the 23rd, it was, generally speaking, to conform to this offensive movement. Gen. von Bülow had, however, made the mistake of attacking prematurely with his II. Army; the combined movement with the III. Army was unsuccessful, and consequently the trend of the fighting drifted westwards to where the advanced guards of the I. Army were coming into contact with the British on the Mons–Condé canal.

When day broke on Aug. 23 Gen. von Kluck had three active corps and Gen. von Bülow one (the VII.), or about 150,000 men and 600 guns, within striking distance of the British force of some 75,000 men and 300 guns. Further, Gen. von Bülow had been for two days successfully engaged against the French V. Army, which had been pushed back some way S. of the Sambre. Not only, therefore, was the British army heavily outnumbered, but it was becoming isolated. The great advantages which the Germans possessed in this respect were, however, neutralized by their lack of accurate information. By the 20th it had not been definitely ascertained that the British Expeditionary Force had completed its landing, and its line of advance when landed was expected to be towards Lille. Not only at the time, but for several days after the battle of Mons, it was believed that the British were based on Calais and the ports near it instead of upon Le Havre and Rouen.

On the evening of Aug. 22 the German I. Army had halted E. of the line Mignault–Laugnée (IX. Corps), Chaussée Notre

FRONTIERS, BATTLES OF THE (MONS)

PLATE V.

Dame de Louvignies-Thoricourt (III. Corps), Silly-Ollignies (IV. Corps), Niova (II. Corps). The III. Reserve Corps had been detached towards Antwerp, while the IV. Reserve Corps had just arrived at Brussels. Army headquarters were at Hal. The II. Cav. Corps under Gen. von der Marwitz was W. of Ath. Gen. von Kluck's task for the 23rd was to continue the advance of his I. Army into the area N.W. of Maubeuge, and he issued orders in which the destination of his various corps were to be as follows: The II. Corps was to be at La Hemaide, the IV. Corps at Baseeles and Strambuges, and the III. Corps at St. Ghislain and Jemappes. The high ground on the S. side of the canal to be occupied. The IX. Corps was to cover the movement on the Maubeuge side. The IV. Reserve Corps to follow in rear as second line. The heads of the IV., III. and IX. Corps were to cross the line Ath–Roeulx at 8:30 A.M.

The German I. Army was thus to march in a south-easterly direction. The British II. Corps on the Mons canal was facing north. Consequently the left of the army of Gen. von Kluck must collide with the II. Corps in the neighbourhood of Mons. As a matter of fact the German commander was in ignorance of the position of the British force; in the orders referred to above there is no mention of the fact that it was along the Mons canal, and, indeed, the German cavalry had reported the ground clear for 50 miles. The march of the I. Army, on the 23rd, was therefore shrouded in the fog of war, and quite early in the day delay was caused by a report that Tournai was held by British troops. These were actually two French territorial battalions, but, under the impression that they were British, orders were sent to the IV., III. and IX. Corps to halt on the Leuze–Mons–Binche road in view of the possibility that it might be necessary to make a wheel to the right so as to envelop Tournai. Later reports showed that the British were in strength on the canal, and that the troops at Tournai, now known to be French, had retired towards Lille. The advance of the German I. Army was therefore resumed. But the orders for this resumption of the march were late in reaching the III. and IV. Corps, with results that reacted on the German chances in the battle.

The left column of Gen. von Kluck's army was the 17th Div. of the IX. Corps, and its march was directed towards St. Symphorien and Villers St. Ghislain. On the British side the I. Corps was on the line generally Harmignies–Peissant, and as it faced a gap between the German I. and II. Armies its share in the battle of Mons was destined to be very small. It was shelled by German artillery, covered in its advance by the 16th Dragoons, but the British casualties were slight, only about 100, and these were chiefly in two batteries upon which the German fire was concentrated. Of active fighting there was none save for some spirited minor actions between the British divisional cavalry and cyclists on the one hand and German patrols on the other. The bulk of the day's fighting fell upon the salient formed by the canal loop round Mons. So soon as Gen. von Kluck had grasped the real state of affairs—namely, that the British were not at Tournai but along the Mons–Condé canal—his plan appears to have been to envelop both the British flanks while bombarding the front heavily with his guns. The envelopment of the British left did not succeed, owing chiefly to the delay referred to above.

The battle opened in earnest about 10:30 A.M. with a bombardment by some batteries of the German IX. Corps which came into action on a ridge to the N. of Orbourg, and from that time onward the guns were gradually extended westwards as battery after battery, first of the IX. and then of the III. Corps, came into action. At 1 P.M. the Germans had established a great superiority of artillery against the front of the British II. Corps. The actual loop of the canal was held by the 4th Royal Fusiliers and the 4th Middlesex Regt., the former being responsible for the bridge at Nimy while the right of the latter regiment held the crossing at Orbourg. At both these places the fighting was very severe, but the British musketry proved a terrible surprise to the Germans, who came on in masses which it was impossible to miss, and the British guns, though outnumbered by the German artillery, gave most effective support. Finally, however, the Germans were able through their superiority in numbers to make a converging attack against the salient from the N. and E., and the British were gradually forced back E. and S.E. of Mons. But the Germans were cautious about pushing into the town, and it was not until after 7 o'clock that the 84th Regt. of the 18th Div. of the IX. Corps entered Mons, where it was thrown for a time into confusion by heavy fire. The British 3rd Div. fell back to a line running E. and W. through Nouvelles.

West of Mons the left division of the German III. Corps attacked the left of the British 3rd Div.; and still farther W. along the canal the right division of the III. Corps, and later towards evening, the advanced guards of the IV. Corps, attacked the 5th Div. of the British. The retirement of the 3rd Div. from the salient round Mons inevitably led to a slight withdrawal of the 5th Div., and by nightfall the II. Corps was on a line which showed an average retirement of some three miles from the canal.

During the late afternoon and evening Sir John French had been receiving disquieting news as to the situation of the French V. Army on his right. At 11:30 P.M. a telegram arrived confirming the reports, to the following effect: Namur had fallen during the day; the French V. Army had been heavily attacked, and was falling back to the line Givet–Philippeville–Maubeuge; Hastière had been captured by the Germans; the Meuse was falling rapidly and had added to the difficulty of defence. In these circumstances Sir John French decided to retreat to a previously reconnoitred line from Jerlain eastwards to Maubeuge, and orders were issued accordingly in the small hours of the 24th. The withdrawal was effected without serious loss, and for a moment Sir John French thought of taking advantage of the fortifications of Maubeuge; but recollections of the fatal attraction of Metz for Bazaine induced him to pass the fortress, and orders were issued at 3 P.M. on the 24th for the retreat to be continued to the line Le Cateau–Cambrai. After Bavai the retreat was handicapped by an incident of terrain, for the Forêt de Mormal compelled the British army to march in two separated portions, the I. Corps E. of the forest and the II. on the west. In the latter corps a crossing of routes had taken place, with the result that the 3rd Div. had changed places with the 5th and was now on the outer flank. Towards nightfall on the 24th the pressure of the enemy became greater on the British left, but the British cavalry division performed excellent service in keeping the enemy at bay, and early on the 25th the retreat was continued, again covered skilfully by the mounted troops. During the night the detrainment of the 4th Div. from England was almost completed, and it moved to its position towards Cambrai.

Meanwhile reports which had been coming in during the day (25th) showed that the French were retiring all along the line, and Sir John French had now to come to a momentous decision. Was he to stand and fight on the line to which the British were now retiring (Le Cateau–Cambrai), or ought he to continue the retreat at daybreak on the 26th? After long and anxious deliberation the commander-in-chief came to the conclusion that the retreat should be continued, and orders to that effect were accordingly issued. The order was complied with by the I. Corps. That corps had been delayed in starting on the 25th, and had only been able to reach the neighbourhood of Landrecies. When darkness fell the Germans sent forward advanced troops in motors and lorries through the Forêt de Mormal, and this culminated in a violent attack on Landrecies, which was, however, beaten off, chiefly by the 4th Guards Brigade. Sir Douglas Haig then proceeded to carry out the orders of the commander-in-chief, and the retirement of the I. Corps was continued in the direction of Guise. In the II. Corps, however, shortly after midnight Sir Horace Smith-Dorrien came to the conclusion that, in view of the fact that many of his troops had only just come in after over 20 hours of heavy and continuous work, and that the enemy were close along his front, it was out of the question to continue his retirement at dawn. He therefore issued orders to fight on the ridge just S. of the Le Cateau–Cambrai road.

When dawn broke on the 26th Smith-Dorrien's force was disposed as follows from right to left: The greater part of the cavalry was between Le Cateau and the Sambre; later it moved to the left flank to get in touch with the French. Cav. Corps of

Gen. Sordet, which all through the 25th was moving in rear of the battlefield to protect the British left. Then came the 5th Div., which held the front from the southern outskirts of Le Cateau to Troisvilles, with the 19th Bde. in support. The 3rd Div. held the centre as far as Caudry, and on the left lay the 4th Div., part of which had moved forward N. of the Cambrai–Le Cateau road the day before to protect the retirement of the II. Corps, but the left of which was now about Esnes. Thence to Cambrai was a gap filled by the 4th Cav. Bde., and later by Gen. Sordet's cavalry corps. The French 84th Territorial Div. was retiring slowly through Cambrai.

The German force on the heels of the British II. Corps was the I. Army, whose commander, Gen. von Kluck, at one time or another before, during, and after the battle was the victim of faulty conclusions. He believed that the whole of the British Expeditionary Force was opposite him; he diagnosed that it was holding a position running N. and S., whereas the line of the II. Corps was almost due E. and W., and he was sure that it was either retreating or about to retreat in a westerly direction. His plan was similar to that which had been tried at Mons, a frontal attack mainly with artillery followed by enveloping movements against both flanks. The II. Corps was to march through Cambrai and the IV. Reserve Corps to Catherieres, thus enveloping the British left. The IV. Corps was to make the attack on the British front from the W. of Le Cateau to Caudry. The III. Corps was to march W. of the Sambre on Le Cateau in order to envelop the British right. The II. Cav. Corps under Gen. von der Marwitz was to pin the British left until the German infantry should arrive upon the field.

Soon after daybreak the British were engaged upon both flanks. On the right some troops of the German IV. Corps entered Le Cateau and some confused fighting ensued, while on the left the 4th Div. became engaged with the II. Cav. Corps of the enemy. Here the 4th Div., after defending an advanced position for some time, fell back slowly to a second line and brought the enemy advance to an abrupt standstill. These events were but preliminaries, and the battle of Le Cateau proper opened with a heavy bombardment, which grew in intensity as the artillery of four German corps came into action. The British artillery made a spirited reply, though heavily outmatched in numbers and weight of metal, and dealt severely with attempts of the German infantry to push forward. These attempts were, however, practically limited to the ground near Le Cateau on the British right, and to the village of Caudry, which now formed a salient in the centre of the line. Throughout the forenoon constant infantry attacks varied by bouts of heavy shelling were made against the latter village, from which about noon the defenders were forced out by artillery fire; but a counter-attack at once regained part of it and the German infantry advance was held up.

It was now about 1 P.M. and the line of the II. Corps was still everywhere intact in spite of the superior numbers arrayed against it. But on the right the situation was becoming grave, for the 5th Div. with its right flank uncovered by the retirement of the I. Corps was being threatened by more and more German columns converging upon the field. Sir Horace Smith-Dorrien realized that the moment had come when at all costs the fight must be broken off if his force was to be saved. He was now faced with one of the most difficult operations of war—that of extricating tired troops from contact with an enemy largely superior in force. Orders were, however, sent to break off the fight and to continue the retirement of the previous days, and the operation was very neatly accomplished with entire success, difficult though it was. Against the exposed flank of the 5th Div. the Germans were now vigorously pressing, and this to some extent precipitated matters, for before the orders for retreat had reached all concerned, the British right had given way before overwhelming superiority of numbers. But the Germans failed to exploit this success, and the withdrawal of the II. Corps, thanks largely to the devotion of the British artillery and to the arrival of Gen. Sordet's cavalry corps on the left, which held off the German enveloping movement in that quarter, was effected with less difficulty than had been expected. Sir Horace Smith-Dorrien successfully withdrew his columns, and marched them swiftly to the Somme at and near Ham, and by the 28th had got the II. Corps safely across the river.

The losses of the British had been severe, and 38 guns had been taken by the enemy. The men were exhausted after the severity of the marching and fighting of the first stage of the war, and a vigorous pursuit by the Germans might have meant disaster for the British II. Corps. The retreat, however, was practically unmolested, for Gen. von Kluck hurried S.W. instead of S., and thus missed a chance not likely often to occur in war.

(F. E. W.*)

**FROST, ROBERT** (1875– ), American writer, was born in San Francisco, March 26 1875. His father was a New Englander and his mother was born in Edinburgh. In 1885 he moved with his parents to Lawrence, Mass., studied in the public schools, and entered Dartmouth College in 1892, remaining there one year. During 1897–9 he was a student at Harvard. During 1905–11 he taught English in the Pinkerton Academy, Derry, N.H., and then for a year taught psychology at the N.H. Normal School at Plymouth. In 1912 he went to England, where he remained three years and published his first two volumes of verse. On his return to America he retired to a farm at Derry and gave much time to active farming. During 1916–20 he was professor of English at Amherst College. His poems portray in realistic fashion every-day country life in New England. Some of the work of his first volume had been denied publication for 20 years, and some of the second for 10 years. He was the author of *A Boy's Will* (1913); *North of Boston* (1914); *Mountain Interval* (1916) and *A Way Out*, a play (1917).

**FRY, SIR EDWARD** (1827–1918), English judge (*see* 11.270), died at Failand, near Bristol, Oct. 19 1918.

**FRYATT, CHARLES** (1872–1916), British sea-captain, was born at Parkeston, near Harwich, Essex, Dec. 2 1872. He entered the service of the Great Eastern Railway Co., and in 1904 became chief officer in their service of vessels plying between Harwich and Rotterdam, in 1913 becoming captain. He continued to navigate his ship, the "Brussels," to Rotterdam and back for the first two years of the World War. At the end of July 1916 it was announced that the "Brussels" had been captured and the captain himself arrested and tried by court-martial on a charge of having attempted on March 28 1916 to ram the German submarine U33 near the Maas lightship. The German authorities stated that Captain Fryatt had confessed during his examination that he had acted under orders from the Admiralty, but the trial was suspiciously hurried and secret, an application for postponement being refused, and no intervention on the part of neutrals was allowed. The captain was condemned to death and shot at Bruges July 28 1916. Half an hour after the execution had been carried out a telegram arrived from the army headquarters at Berlin ordering the sentence to be postponed. The news of the execution aroused great indignation in England, and on two occasions it was stated by Mr. Asquith in the House of Commons that due reparation would be exacted for this and similar murders. Ample provision was made for Captain Fryatt's family, his widow being awarded a pension of £100 a year over and above the amount to which she was already entitled under the Government compensation scheme, while the Great Eastern Railway Co. also gave Mrs. Fryatt an annuity of £250 a year for life. The captain's body was on July 7 1919 brought from Belgium to England. A memorial service was held at St. Paul's on July 8, and the body was buried at Dovercourt church, near Harwich.

**FUEL** (*see* 11.274).—Civilization on its physical side is based on fuel. Of all the powers of nature which have been turned by man to his use and convenience, fire stands out with a distinction which is unique. The kindling of the first fire of dried leaves and branches by our prehistoric ancestors marked the beginning of the transfer of this mighty power from the gods to man, and new possibilities of prodigious import were opened up. With fire at his command, a new dividing line was established between man and the lower animals, and a higher and more social standard of living became possible. The horrors and dangers of the darkness of night were greatly mitigated, social instincts were aroused

through the nightly gathering round this new source of light and warmth, while imagination and thought were stimulated. The charred stick supplied the budding artist with his first pencil, while the glowing embers were the laboratory furnace in which the coming chemists and metallurgists made their first observations of the effects of heat on rocks and stones. Fire, first automatically and then deliberately, became the test to which all materials were submitted. The arts of the craftsman were based on these observations. The smelting of metals, the bending of wood, the singeing of skins, the melting of gums and the boiling of water started a whole train of new possibilities, each step in discovery opening the way to new adventures. It is no exaggeration to say that the practice of observation and experiment, on which the physical science of to-day is founded, had its origin in the first fire kindled by man. In the management of the wood fire the first lessons in the properties of fuel were learned. The flaming stage, followed by the steady and more concentrated heat of the glowing embers, naturally led to the collection of more massive embers by the control of the earlier stages of combustion, thus leading up to charcoal burning, by which the worker in metals was supplied with an ideal fuel for his operations. Thus the carbonization of raw fuel as a means of raising the availability of its potential therms had its origin in the far past.

It is unnecessary here to follow through the ages the romantic history of the association of fuel with civilization. Enough has been said to justify the opening remark that civilization on its physical side is based on fuel. This interrelation developed new features during and after the World War of 1914–8, and the future production and use of fuel in England and other countries has become closely associated with social ideals which involve the raising of the standard of living among the mining class.

### Fuel Resources of the World

Before considering in detail some of the fuel problems of the immediate future, it may be well to pass in review the fuel position of the world in 1921, as it was disclosed by the most recent figures of production.

*Coal and Lignite.*—According to the estimate of the United States Geological Survey in 1920 the total world output of coal, including 143 million tons of brown coal and lignite, amounted to 1,300 million metric tons (*see* Coal). This is within 3% of the maximum output, which was reached in 1913 and 1918. Of this total output, the United States produced 45%, Great Britain and the British Empire 22%, Germany 19%, while other countries ranged from 2½% downwards. One of the most significant features of this survey is the remarkably rapid development in the winning and use of brown coal and lignite on the continent of Europe and particularly in Germany. The output of brown coal and lignite in Germany in 1919 had reached 93·8 million tons, but this was overtopped in 1920 by an output of 111·6 million tons, out of a total output of 140·7 million tons on the continent of Europe that year. The output of ordinary coal in Germany for 1920 was 140·8 million tons.

The brown coal industry in Germany is of old standing, and its rapid development in recent years is based on sound knowledge and experience. Though in its natural state a less concentrated fuel than bituminous or anthracitic coal, brown coal has many points in its favour. The chief of these is the low cost at which it can be won as compared with ordinary coal. Where extensive deposits of great thickness occur, these can be worked opencast and excavated by machinery. The winning of brown coal is thus on an altogether different basis from ordinary coal-mining with its deep and costly underground roads and workings which involve heavy costs for timbering, pumping and ventilation. The manual labour required is much smaller in amount for a given output, and is of a less highly specialized type, while the special dangers and uncertainties of coal-mining are practically absent. The capital charges, being mainly on surface roads and on excavating machinery, are relatively light as compared with the heavy initial and permanent charges involved in the sinking and equipment of shaft or mines. Brown coal, though it contains from 40 to 60% of water, is to-day by far the cheapest source of thermal units. Its further manufacture by drying, briquetting and carbonization can be carried out close to the point of excavation and under conditions favourable to production on a large scale, and therefore at a low cost. The glowing accounts of this development which appeared in the technical press during 1919–21 may have been somewhat exaggerated; but the solid fact remains that in 1920, with a production of 111 million tons of lignite in addition to ordinary coal, Germany had already faced the fuel problem of the future so far as she herself was concerned. According to the extent to which Germany could meet her own requirements for heat and power by the development of lignite, peat and water-power, the output of her coal-mines would be set free for export.

It is not surprising that Germany's example has been followed, not only in Central Europe, but in Victoria (Australia) and in Canada. In Victoria extensive deposits of brown coal exist in Central Gippsland, which are estimated by Mr. H. Herman, the Director of Geological Survey, to contain 30 thousand million tons. The main deposits near Morwell are hundreds of feet in thickness, and lend themselves admirably to opencast working on an enormous scale. Considerable progress has already been made in the development of these deposits; and since the commencement of operations in 1916, 400,000 tons of brown coal had been mined and sold by 1921. When the excavating methods become more perfectly organized, it is expected that the coal will be produced at the mines at 2s. 3d. per ton. It contains from 40 to 50% of water, so that in heat value two tons is equal to about one ton of ordinary coal. A 50,000-kilowatt generating station was in 1921 being installed at Morwell for the transmission of current to Melbourne. It was intended to establish a plant at the mines for briquetting and carbonizing, so that fuels of higher availability might be produced from the raw coal. In 1920 a sample of this coal was received in England, and experiments on its carbonization were carried out at the Government Fuel Research Station. In the Dominion of Canada experiments were in progress in 1921 on the briquetting and carbonization of the brown coals of Manitoba and Saskatchewan. These experiments were being carried out under the auspices of the Dominion and of the Province of Saskatchewan.

*Oil and Oil Shales.*—Of oil (*see* Petroleum), next to coal the chief natural source of fuel, the world's output for 1920 was about 97 million tons, of which the United States produced 64·8%, Mexico 23·3, Russia 3·5, the Dutch East Indies 2·5, India 1·2, Rumania 1·1, and Persia 1·0. The oil output amounted to 7% of the fuel output of the world, reckoned in tons. If reckoned in potential therms, the figure would be raised to 10 per cent. As the United States has extensive oil interests in Mexico, it may be taken that in 1920 she controlled 75 to 80% of the total output of the world. It is therefore significant that, in official quarters, grave anxiety has been expressed as to the probable exhaustion of these resources in view of the rapid development in the use of motor spirit for road transport and of fuel oil for transport by sea. The following extract from a statement by Mr. J. O. Lewis, Chief Petroleum Technologist to the United States Bureau of Mines, expresses clearly the American view:—

"The United States Geological Survey during 1910–20 has made several estimates of the quantity of oil left in our oil fields. The most recent estimate, that of David White, indicates that about 40% of the oil had been brought to the surface, and that the 60% remaining underground would last barely 20 years at the present rate of consumption. As the period in which an oil field can be made to yield its oil is not wholly within the control of man, the domestic production will undoubtedly be spread over a much longer period than estimated; but, on the other hand, the peak of production will be passed long before 20 years, and thereafter production will be at a declining rate. Of course, such estimates are by no means infallible, as many obscure factors are involved. However, this statement represents the opinion of the agency best qualified to make such an estimate, and is indicative of a condition which, were there no other solution to the problem, would be highly unsatisfactory, and would be viewed by the automotive industry with the greatest concern. For, even were the estimate unduly pessimistic, and the actual reserve double, the condition would be unsatisfactory.

"The preceding statement refers only to the oil from oil wells in the United States. Fortunately there are enormous undeveloped

resources in the rest of the world. The petroleum resources of this country have been developed and depleted in a ratio far beyond that of other countries, so that although we are producing to-day two-thirds of the world's production, the opportunities elsewhere for increasing production are much greater than in the United States. Geologists and those well-informed on foreign resources believe that in all probability the world contains enormous reserves of oil that can be obtained upon demand. Although to obtain oil from these reserves may not be as satisfactory as to obtain it within the confines of the United States, the outlook tends to assure the future of the internal combustion engine.

"Fortunately oil may be obtained from other sources than oil fields. In various parts of the United States, particularly in Colorado, Wyoming and Utah, are enormous bodies of oil shales from which oil may be obtained by destructive distillation, as benzol is obtained from coal. The United States Geological Survey has estimated the quantity of oil locked up in the richer shales of the three States mentioned as perhaps ten times the amount of the oil reserve in the oil fields. In Scotland the retorting of oil from oil shales has been on a commercial basis for more than 50 years, and antedates the oil industry in the United States. Commercial and semi-commercial experiments are being made in order to determine whether the oil shales of the Western States can be mined and retorted profitably in competition with petroleum from oil fields. This problem has not yet been solved, but these shales constitute a latent reserve that protects the future needs of the country for motor fuel as far as these needs can be foreseen. However, oil cannot be obtained from the shales on a large scale without heavy investments and the development of the industry must be spread over many years. Also, when the time comes, the consumer will probably have to pay more for his gasoline."

The oil shales not only of the United States, but of the whole world, await development as a source of oil fuel. The commercial possibilities of this development depend almost entirely on the relative cost of production and the selling price of natural oil and shale oil. In comparing the cost of production of natural oil from wells and of oil produced by distillation from shale, long experience has shown that in any field which is considered worthy of commercial development the cost of the oil at the wells should not exceed one penny per gallon, or 25s. per ton. In favourable cases it is only a fraction of this amount. In the shale field the shale has to be mined and transported to the retorts in which it is distilled, and the earthy residue, which amounts to from 15 to 17 cwt. for each ton distilled, has to be handled and disposed of. Labour and fuel have to be supplied for the retorting process and the retorts have to be kept in repair. With selected shales a yield of 30 to 40 gal. of crude oil per ton of shale may be obtained. The mining and retorting costs will amount to at least 10s. per ton, without capital and general charges, or 3d. per gallon for the crude oil as compared with the above figure of one penny per gallon at the wells. It is clear that the initial cost of crude oil obtained from shale puts it quite out of court in competition with natural oil, except in situations so far from oil wells that the extra cost is compensated for by that of transport of natural oil. It is clear that, in times of plenty, the natural oil can, if necessary, be sold at a price of one penny per gallon, which will at least pay the cost of production; the shale oil works on the other hand would have to sell at a loss, or to shut down and disband the large staff of skilled workers required for the prosecution of the industry.

The history of the oil industry during the period 1870–1920 shows a succession of waves of over-production and low selling prices, as new oil fields have been developed. The effect of these periods of plenty and of low prices has on the whole been to develop consumption of oil as a fuel; but their effect on the shale industry of Scotland has been to make the profitable running of the industry so speculative that it has never been possible to develop it on a really large scale, though ample supplies of shale are known to exist there. With natural oil, cost of production *per se* has very little to do with the fixing of the selling price, but with shale oil cost of production is the vital consideration. The best hope for the development of the shale-oil resources of the world appears to depend on a continuance of the interest recently shown in the United States in this question as being of vital importance to the industrial welfare of that country. Great natural resources in oil shales have been proved to exist; it only remains to develop systems of mining and retorting on the best modern lines, by which shale oil can be placed on the market at a minimum cost. Though in the opinion of experts in Great Britain this can never approach the actual cost of production of natural oils in existing fields, shale is thereby not necessarily excluded as one of the more important sources of oil fuel. First cost is only one among the conditions which will determine this development.

The production of oil by the carbonization of bituminous coal is also receiving much attention in the United States, as well as in Great Britain and Germany. This problem involves economic questions which do not arise in connexion with oil shales. Chief among these is the fact that, while in the distillation of shale about 70% of the shale distilled is a valueless earthy residue, 60 to 70% of the bituminous coal is retained after carbonization as a smokeless fuel of a higher value for domestic purposes than the original coal.

*Peat.*—The scarcity of fuel in the United Kingdom during the World War led to considerable pressure upon the British Government for the establishment of a serious inquiry into the possible development of peat. The matter was considered by the Advisory Council of the Department of Scientific and Industrial Research, resulting in the institution of the Fuel Research Board, by whom an Irish Peat Inquiry Committee was appointed. The history of this inquiry has been dealt with in the published reports of the Fuel Research Board.[1] As the subject was recognized as one of world-wide importance, Prof. Pierce Purcell was appointed Peat Investigation Officer to the Fuel Research Board in 1919, and through him close touch was maintained with the principal peat developments in Europe and America. In the summer of 1920 Prof. Purcell visited Canada and the United States, and investigated the work of the Peat Committee of the Canadian Government at the Alfred Bog, near Ottawa. In the following summer he visited some of the more important peat stations in Germany, Denmark and Sweden.

In Germany the Wiesmoor peat station has been in operation since 1910. The peat is dredged, macerated and spread on the surface of the bog to dry. By stacking under cover, the moisture of the peat blocks can be reduced to 25% solely by air-drying. For steam-raising purposes two tons of air-dried peat are equal to about one ton of coal. At Wiesmoor eight water-tube boilers are fired with peat. The average fuel consumption is stated to be from 2·7 to 3 kilos of partially dried peat sods per kilowatt hour, and the cost of the peat is taken at five marks per ton. A scheme was stated to be on foot for the establishment of a line of peat generating stations from Königsberg on the east to Wiesmoor. The promoters of this scheme appear to have ignored the fundamental difficulty which applies to the winning of peat in quantities sufficient to meet the day-by-day requirements of any large central station. When it is realized that the peat deposit in a good bog 20 ft. deep is only the equivalent of a 12 or 14-in. seam of coal, it will be evident that even an output of 1,000 tons a day of air-dried peat involves the laying out and development of an enormous surface. At the Zehlonbruck station, near Königsberg, it was proposed to use 920,000 tons per annum, or about 2,500 tons per day. Prof. Purcell states that to win mechanically 900,000 tons of air-dried peat in one season at least 4,500 men, women and children would be required, and the area over which the spreading and drying operations would extend could not be less than 9,000 ac., or say 15 sq. miles. He suggests that, in dealing with any production over 60,000 to 80,000 tons per annum from any single district, the difficulty would increase as the square of the production; and he considers that it is only by the development of these smaller units that progress will be made. There was evidence in 1921 that a steady development on these lines was in progress in Germany.

In Canada and in Ireland the application to local conditions of mechanical cutting or dredging, maceration, air-drying and harvesting has been studied with encouraging results. In the summer of 1920 peat was cut, macerated, spread on the bog at Turraun in Ireland, air-dried and harvested there, and a hundred tons of this air-dried peat were sent to H.M. Fuel Research

[1] Reports of the Fuel Research Board for the years 1918–9, and on the winning, preparation and use of peat in Ireland; reports and documents.

Station, where some interesting experiments were carried out on its use for boiler firing and for carbonization. The peat, when it reached the station, contained about 27% of moisture. After having been kept under cover for some months the moisture was reduced to about 17 per cent. This peat is in the form of hard blocks of various lengths, up to about 10 in. with a cross section of something like 2 by 2 inches. Its density is rather under 1, or about twice that of the ordinary hand-cut sods made on the same bog. The blocks can be cut and sawn like hard wood, and they stand transport with very little breaking up into "smalls." In this respect they contrast very favourably with the ordinary hand-cut sods, which break down seriously in transport by rail or road. Steam-raising trials have shown that this material is an excellent boiler fuel, and that it lends itself admirably to carbonization, either in vertical retorts at temperatures between 750° and 850°C. or in steel retorts at 550° to 600°C.

It is evident that maceration of the freshly cut or dredged peat is well worth the small expenditure of power which it entails. When spread on the surface of the bog it dries much more quickly than ordinary cut peat, while in drying a shrinkage occurs which almost doubles the density of the dried product and so produces a fuel which can be stored, transported and used under much more favourable conditions than the ordinary air-dried sods.

*Alcohol.*—In view of the threatened shortage of petrol in England in 1918, Mr. Walter Long appointed a committee to consider the possibilities of alcohol as a motor fuel (*see* ALCOHOL). The report of this committee was considered by the Privy Council Committee for Scientific and Industrial Research, and it was recommended that the Fuel Research Board should be charged with the duty of investigating the technical and economic problems which are involved. As a first step to this end Sir Frederick Nathan was appointed Power Alcohol Investigation Officer. A preliminary survey was published in July 1920.[1]

For the complete replacement of imported petrol by alcohol it was estimated that 250 million gallons of 95% alcohol would be required. To produce this from grain (barley), potatoes or mangolds, the following quantities would be necessary:—

| | Tons | | Acres | | Raw Material | |
|---|---|---|---|---|---|---|
| | Required for 250 million gallons | United Kingdom Production 1919 | Required for 250 million gallons | Under Crop in 1919 | Average Price per ton 1919 | Cost per gallon of Alcohol |
| | | | | | £ s. d. | s. d. |
| Grain (barley) | 4,170,000 | 1,288,035 | 5,593,293 | 1,870,087 | 21 4 0 | 6 0 |
| Potatoes | 12,500,000 | 6,312,000 | 2,118,644 | 1,218,774 | 8 10 6 | 8 6 |
| Mangolds | 25,000,000 | 7,769,000 | 1,282,513 | 471,759 | 1 10 0 | 3 0 |

These figures were not encouraging, and generally it may be stated that the production of alcohol in any considerable quantities from vegetable materials grown in the United Kingdom is not economically possible, owing to (1) insufficient acreage; (2) the high cost of cultivation and harvesting; (3) the high cost of manufacture; and (4) the fact that the most suitable raw materials are also important food-stuffs. There was for these reasons no prospect in England of replacing any considerable quantity of petrol by home-produced alcohol. Moreover, it was unthinkable that land, for even a fraction of the quantity of the raw materials in the foregoing table, could be used for such a purpose when, for food itself, a week-end supply only was assured from the home production. It was, however, considered desirable to make a further study of the growth of mangolds and of Jerusalem artichokes for this purpose, and experiments were in progress during 1919–22. From these it appeared that it might be possible to grow artichokes for the supply of a limited quantity of alcohol for special purposes, such as aviation. An examination of the artichoke stems indicated that it might be possible to convert them by a simple treatment to paper pulp. Should this prove to be the case, both products would be cheapened.

[1] "Fuel for Motor Transport": an Interim Memorandum by the Fuel Research Board.

Investigations as to the possibilities of producing alcohol in the British Empire overseas indicate that, in the sugar-growing countries, molasses, from which alcohol might be obtained, is undoubtedly wasted, but that the wasted quantities are comparatively small, and in most cases would be insufficient, if so utilized, to meet even local requirements for alcohol. Alcohol might be made from suitable crops grown specially for the purpose in those British dominions and colonies where labour is available, and used to supplement or take the place of supplies from other sources. Some such course may be specially desirable where petrol is dear and difficult to obtain, for instance in the E. African protectorates and W. African colonies, which are very dependent on motor transport for their development.

The use of cellulosic materials was not yet possible in 1921, because although research work was in hand to find a process that could be employed on a commercial scale in those regions where such materials exist in sufficient abundance, it had not so far led to any definite results. Where, however, materials capable of easy hydrolysis exist, as for instance is the case with waste rice straw, the large-scale experiments in Burma, under the auspices of the Burma Oil Co., appear to indicate that the joint production of alcohol and paper should be a commercial possibility.

Until alcohol can be made from waste materials which can be collected and treated at small cost, it does not seem likely that British Empire-produced alcohol can be imported into the United Kingdom on any considerable scale; it is improbable that it will be produced cheaply enough, or in sufficient quantities, for export, even by those overseas portions of the Empire which may produce it in this way for local consumption.

### USES OF COAL AS FUEL

Since coal is likely to remain the chief source of fuel for the world at large, the problems of its winning, preparation and use still occupy the foreground in all serious consideration of the subject. We know that in 1913 the output of coal of the mines of the United Kingdom was approximately 287 million tons, of which 98 million tons were exported. Out of the 189 million tons consumed at home, 35 million tons represented the domestic use, and the remainder was taken for industries as follows:—

| | Million Tons |
|---|---|
| Railways | 15·6 |
| Coasting Steamers | 2·5 |
| Factories | 60·0 |
| Mines | 20·5 |
| Iron and Steel | 31·0 |
| Other Metals | 1·3 |
| Brickwork, Potteries, Glass and Chemicals | 5·6 |
| Gasworks | 18·0 |

The uses of coal as fuel may be classed under three main heads: —(1) production of heat and light for domestic purposes; (2) production of heat for industrial purposes; (3) production of power for industrial purposes and for transport. Reclassifying the above figures under these three heads, we find that the consumption was as follows:—

(1.) *HEAT and LIGHT for domestic purposes.*

| | Million Tons |
|---|---|
| Directly burnt as coal | 35 |
| One-third of the total used by gas undertakings | 6 |
| One-half of the total used by electrical undertakings | 3 |
| | 44 |

| | Million Tons |
|---|---|
| (2.) *HEAT for industrial purposes.* | |
| Iron, steel and other metals | 32 |
| Bricks, pottery, glass, cements | 6 |
| Paper, textiles, food-stuffs, fertilizers, chemicals, as steam | 20 |
| | 58 |

| | | 189 |

These figures show that 141 million tons, or three-fourths of the coal used in the United Kingdom, was burned in the raw state; that 35 million tons, or nearly one-fifth of the total consumption was used in the raw state for domestic heating; and that 97 million tons, or one-half of the total consumption was used in the raw state for steam raising. Before considering the technical and economic problems which are involved in the replacement of raw coal as a fuel by the products of its carbonization, gas, petrol, oils and coke, we shall review the position of these great outlets for raw coal, domestic heating and steam raising.

*Domestic Heating.*—The domestic use of coal in the raw state affects the widest range of consumers in most civilized communities. In Great Britain the consumption per head of the population is in the neighbourhood of one ton per annum. In Ireland peat is still the chief domestic fuel, about six million tons of air-dried peat being consumed per annum. In no other country but Great Britain does the consumption of raw coal for domestic purposes reach the high figure of one ton per head per annum. The ample supplies and the low price of bituminous coal for centuries prior to the World War have established the open room fire and the kitchen range on a popular foundation in Great Britain from which it is difficult to displace them. The British climate has had much to do with the popularity of the open room fire, the radiation from which can be so readily modified to meet the rapid changes of humidity and temperature which are liable to occur almost from day to day during the year. Only during exceptional winters, when really low temperatures have continued for weeks at a time, has the open fire broken down as a means of maintaining English homes at a habitable temperature. The work of Dr. Margaret Fishenden on open fires has definitely shown that, under reasonable conditions of firing, 20% of the total potential heat of the raw coal is radiated into the room, and that a further 20 to 30% is given up to the fabric of the building before the waste products of combustion leave the chimney. Smoke and soot are, however, an unduly heavy price to pay for the transient cheerfulness of the flaming coals in a well-stoked fire, especially when we remember that over long periods the ordinary fire is only smouldering and dreary-looking. The coal-fired kitchen range, unlike the open room fire, has few if any sentimental associations and its replacement by gas-cookers and coke-fired water-heaters is only a matter of time.

In northern and central Europe, and in the United States and Canada, where really low winter temperatures prevail, close stoves and central heating systems are universally used, and the smoky combustion of bituminous coals has never gained a footing. In the United States and Canada anthracitic coals for domestic purposes are regarded as a necessity, and the Governments of these countries give every encouragement to schemes for the conversion of bituminous coals into smokeless fuel so as to avoid the transport from great distances of anthracitic coals. On the social side of civilization it is no exaggeration to say that the cheap and plentiful supplies of bituminous coal in Great Britain have not been an unmixed blessing. Even on the industrial side this is true, for it has led to the formation of habits of reckless extravagance in the use of fuel, which are so deeply rooted among workmen and manufacturers that it will take many years of high fuel prices to eradicate them. The gas undertakings of the United Kingdom have, however, done much to popularize the use of gas and coke for the replacement of raw coal for domestic use; and there is every prospect that a considerable proportion of the raw coal burned for domestic use will be displaced by the developments in the production of town gas on newer and more economical lines, and by the increased use of gas-works coke for domestic heating.

*Steam Raising.*—The fact that one-half of the coal used in Great Britain is consumed in raising steam for heating purposes and for power production, places the problems of fuel efficiency in this connexion in the forefront from an economic point of view. On the theoretical side these problems lend themselves to simple and direct treatment.

Steam-boiler efficiency depends first on the perfect combustion of the fuel, second on the utilization of the radiant heat of combustion, and third on the utilization of the sensible heat of the gaseous products of combustion before they are dismissed to the chimney. The heat for the conversion of water into steam has to pass through steel plates or tubes, and the rate at which this transference takes place is determined by the different temperature of the two sides of the plate or tube. The lower the temperature on the water side and the higher the temperature on the furnace side, the greater will be the amount of heat which is passed into the water, and the higher will be the evaporative efficiency of that portion of the boiler. Direct radiation from the burning fuel is by far the most effective means of maintaining the temperature on the furnace side of the plates and therefore of obtaining the highest evaporative efficiency per sq. ft. of metal surface. On the water side of the plate or tube the temperature can be kept down only by the maintenance of a very rapid circulation of the water over the metal surface. With adequate water circulation sufficient heat for the evaporation of 60 to 80 lb. of water per sq. ft. per hour can be safely passed through the metal. With inadequate circulation the metal may be raised to a destructive temperature, and the boiler may be ruined. In the ideal boiler the maximum proportion of the radiant heat of combustion ought to be absorbed by metal surfaces provided with ample water circulation on their inner side. The utilization of the sensible heat of the products of combustion involves the transfer of the heat of the gases to the metal by convection; the molecules of gas must actually come in contact with the metal surface. Rapid circulation is required in order to obtain this, and high velocity of the gases must be maintained. The work of Nicholson on this subject has received considerable attention during recent years and has to some extent been applied to boiler design. The importance of the direct absorption of the radiant heat of combustion is not as yet so generally recognized, but is likely to lead to important results in boiler design. The theoretical knowledge as to the utilization of the heat of combustion in boilers is still somewhat in advance of even the best engineering practice in steam-boiler construction. Unfortunately average practice still lags far behind the best knowledge on the subject.

Coal as ordinarily burned suffers from the disadvantage that it is not a homogeneous fuel like gas, oil or coke, but is in effect a mixture of these three forms of fuel. The only way in which coal can be made to approximate to a homogeneous fuel is by pulverizing it so that its particles are so fine that, when mixed with air, they at once ignite and burn like a jet of gas or a spray of oil. The degree of fineness required to produce this effect involves grinding till 80% of the coal will pass through a screen of 200 meshes to the square inch. For metallurgical and other high temperature purposes the advantages which result from pulverization may more than compensate for the cost of grinding and for the heavy initial cost of the grinding and distribution plant, but for steam raising it is still an open question whether the gain in the efficiency of combustion is sufficient to compensate for the greatly increased cost which is involved. In the best steam-

raising practice the disadvantage due to the non-homogeneity of raw coal as a fuel has been met by the design and working of the boilers, while by the use of automatic stoking and ash removal, the boiler house charges under these heads have been greatly reduced. In comparing the best practice on these lines with the most recent experiences in connexion with pulverized fuel in America it is still doubtful whether the latter can be justified on the score of expense.

The valuable papers of Mr. D. Brownlie[1] throw a much needed light upon the use of coal for steam raising. His analysis of the statistics which he has collected shows that the amount of coal used for steam generation in Great Britain for heat and power production is from 75 to 100 million tons per annum, or about one-half of the whole coal consumption. His conclusions as to the comparative efficiency of the numerous boiler plants he personally examined during seven or eight years, and the extension of these conclusions to cover the whole steam-raising practice of the United Kingdom, supply material on which some broad generalizations may be based. He divides the boiler installations of the United Kingdom into three classes—bad, average and highly efficient. Of the total number he classes: 10% as bad, 85% as average and 5% as highly efficient. As regards the efficiencies of each class, with water-tube boilers the bad give 61%, the average give 69%, and the highly efficient give 82%, while with Lancashire boilers the bad give 49%, the average give 60% and the highly efficient give 79%.

If we take the minimum figure of 75 million tons as the amount of coal annually used for steam raising in Great Britain, it is clear that the scope for economy is enormous; for even a moderate increase of efficiency of 10% over all would result in a saving of 7½ million tons per annum. Mr. Brownlie's own experience of the savings to be effected by a reorganization of plants leads him to take a much higher saving as a possibility. In the case of the colliery steam boiler plants, the average efficiency of which he places at 51%, he estimates that the coal bill for all the British colliery plants is 18½ million tons, and that the efficiency might easily be raised by 10 to 15%, while by the systematic use of colliery waste a further saving of salable coal would be realized. These facts and figures are well worth careful study of all who are seriously interested in fuel economy. They show the enormous possibilities existing for fuel economy, apart from any new revolutionary discoveries.

Before we leave the subject of steam raising, the use of gas, oil and coke for this purpose may be referred to.

*Gas.*—A considerable amount of experience has been accumulated on the use of gas for steam raising. This experience covers a wide range of gases from blast-furnace gas of about 100 B.Th.U. per cub. ft. to coke-oven gas of over 500 B.Th.U. With the lowest grade gas the thermal efficiency in ordinary practice has generally been of a low order, but with proper care in boiler setting and firing there is no reason why a thermal efficiency of 80% should not be reached, even with low grade gas. The evaporative efficiency per sq. ft. of heating surface however is low, and in ordinary blast-furnace practice it is found that when coal-firing is replaced by gas, a larger number of boilers is required for the evaporation of the same amount of water.

With coke-oven gas there is no reason why the highest thermal efficiency, as well as a high evaporation efficiency per sq. ft. of heating surface—should not be obtained. From an economic point of view, however, the use of high-grade gas for steam raising can only be justified when it is a waste product for which there is no other outlet. As fuel for steam raising, the availability of the therms in coke-oven gas is only from 10 to 15% higher than that of the therms in the form of raw coal, or, with coal at 25s. per ton, about 1·2d. per therm; but for distribution as town gas its value is from 2·5d. to 3d. per therm, while for use in internal combustion engines its value would be at least as high. For a possible gain in thermal efficiency of from 10 to 15%, it will obviously not pay to produce gas as a fuel for steam raising, except under very special conditions.

*Oil.*—As fuel for land boilers, oil is definitely superior to coal in many respects. Chief among these are the ease with which it can be transported, stored and handled, its flexibility as a fuel, and the high efficiency with which it can be burned. These advantages would probably justify a price of 50 to 100% higher than that of coal. As fuel for the ships of the navy, all the above advantages over coal are emphasized, and in addition to these are the greatly enlarged range of action and the possibility of oil bunkering while at sea. As fuel for the ships of the mercantile marine its advantages are now so fully recognized that the only limits to its extended use are the uncertainty as to future supplies and as to its price. In 1914 there were on Lloyd's Register 364 steamers of 1,310,000 tons fitted for burning oil fuel, whereas in 1921 the total was 2,536 vessels of 12,797,000 tons. The following comparison shows the division of motor-power in the two years:—

| | Percentage of total gross tonnage | |
|---|---|---|
| | *1914* | *1921* |
| Sail power only | 7·95 | 5·05 |
| Oil etc. in internal combustion engines | 0·47 | 2·00 |
| Oil fuel for boilers | 2·62 | 20·65 |
| Coal | 88·96 | 72·30 |
| | 100·00 | 100·00 |

It will be seen that only 72% of the tonnage of the British merchant marine in 1921 required coal, while in 1914 the figure was 89%.

*Coke.*—Much useful work has in recent years been done by the London Coke Committee on the use of coke and coke breeze for steam raising. This has led to the development of the "Sandwich" system of firing with a mixture of coke and bituminous slack. This system, which is in operation in London, Manchester and elsewhere, consists of feeding from a divided hopper on to the chain-grate stoker, coal slack and coke in superimposed layers, the coal being uppermost. With a natural draught of only ·25 in. the coke layer may be from 5 to 6 in. in thickness. This layer prevents the percolation and consequent loss of coal dust through the grate. The coke layer being relatively porous permits the passage of air required for the combustion of the coal under favourable conditions, so that little or no smoke is produced. When coke alone is used on a chain grate it is difficult to maintain a sufficiently high temperature to ensure its ignition near the front of the grate. Under the Sandwich system the ignition temperature is maintained well to the front of the grate by the flame produced from the layer of slack. Each fuel therefore helps the more efficient combustion of the other. When coke is used by itself for steam raising, special provision has to be made to secure that its ignition takes place as near the front of the grate as possible. If this is secure, advantage can be taken of the high radiating efficiency of the bed of incandescent coke by the provision of ample water-cooled surfaces for the direct absorption of the radiant heat.

Direct combustion of coal is likely to maintain a leading place in steam raising for many years to come; and there is no direction in which the scope for increased economy and efficiency is so obvious and so extensive. By the closer association of steam electric-generating stations with gas-works and coke-ovens the use of the products of carbonization, gas, oils, tar and coke, may supplement the use of raw coal to some extent and may lead to higher efficiency and economy of fuel, but this form of association must be carefully thought out in each particular case. Certain general principles which affect this form of association can be laid down, but the purely local and individual condition must always determine the application of these general principles. Their merely superficial adoption will only lead to disappointment and loss. This aspect of fuel economy is referred to below in connexion with carbonization and gasification as a means of sorting out the elements of raw coal into fuels of higher availability and convenience, but it may be said at once that up to 1921 no case had been made out for the general replacement, by fuels of higher availability, of raw coal used for steam raising. There is every reason therefore for the concentration of skill and enterprise on the general application of the well-established principles which govern the most efficient use of raw coal for steam raising. In Great Britain alone it is certain that tens of millions of tons of coal per annum might be saved in this way.

Apart from steam raising the direct combustion of raw coal in industry does not bulk very large in the general fuel bill. In the metallurgical industries coke and gas are the more important fuels, though considerable quantities of raw coal are still used in steel-making. In pottery and brick-making raw coal is still the chief fuel, but movements have been set on foot which may lead to the more extensive use of gas. In the Portland cement industry raw coal is likely to remain the fuel, as it can be used in pulverized form in rotary cement kilns with high efficiency.

### Power Production by Internal Combustion Engines

While by far the larger proportion of the power requirements of the world is at present supplied by steam boilers and engines, the

[1] *Engineering*, July 12 and 19, 1918; July 25 and Aug. 1, 1919; Dec. 10 and 17, 1920.

production of power by the direct combustion of fuel in internal combustion engines has taken an increasingly important place (*see* INTERNAL COMBUSTION ENGINES). In 1900 great hopes were entertained that gas-engine units of large size would be used for the generation of electricity at central stations. Great difficulties have however been experienced in maintaining gas-engine cylinders of large size, and the tendency for some years previous to 1920 was to keep down the size of the individual cylinders and to multiply the number of cylinders running on one shaft. Under these conditions the size of the unit engine is necessarily limited to 1,000–2,000 horse-power. Even with units of this size the cost of maintenance may be high, and considerable stand-by plant has to be kept in reserve. Sir Dugald Clerk has estimated that, in Great Britain, more than half a million B.H.P. per annum was derived in 1920–1 from gas-engines combined with suction and other gas producers. The Diesel type of oil-engine also made great progress during 1910–20 on land as well as on sea.

The internal combustion engine made the most remarkable developments after 1910 in its application to motor vehicles and to aeroplanes. The fuel required for this purpose must conform to certain definite requirements, the most fundamental of which is that it must be an inflammable liquid which can be depended on to vaporize on mixture with air at a sufficiently low temperature to ensure that the mixture can be fired in the cylinders of the engine by an electric spark. Petrol or gasoline is the most widely used fuel for this purpose. It is a mixture of the more volatile hydrocarbons which are obtained in the fractional distillation of natural petroleum. It is also obtained from natural gas by compression or cooling, or by oil-stripping.

The enormously increased demands during recent years led to the adoption of cracking processes, by which during distillation the heavier and less volatile fractions of the crude oil are partially broken up into hydrocarbons of a volatility which brings them within the range covered by the motor-spirit requirements. It is estimated that the development of cracking methods in the United States has added 10% to the yield of petrol obtained from the crude oil; while other improvements in collection and refining have added a further 5 to 6%. In 1909 the yield was 10·7%, while in 1918 it had risen to 26·1%. Thus fully one-fourth of the crude oil refined in the United States is being put on the market as petrol. The petrol imported into Great Britain in 1920 was about 250 million gal., or 830,000 tons.

The only sources of motor fuel in Great Britain are shale oil-works, gas-works and coke-ovens. From the shale oil-works about four million gallons of petrol per annum might be obtained, and from gas- and coke-works about 20 million gallons of benzol, though in 1921 the output was much less. Benzol is an excellent motor fuel for land purposes, alone or mixed with petrol.

### CARBONIZATION AND GASIFICATION

In connexion with the fuel problems of coal in their wider aspects, the operations of carbonization and gasification can be most conveniently considered as *processes for the sorting out of the constituents of coal into fuels of various degrees of availability and usefulness*. Though the hydrocarbons and their derivatives which occur in, or are derived from, coal by destructive distillation must continue to have a deep interest and an economic significance from the chemical point of view, they are relatively insignificant when the use and disposal of hundreds of millions of tons as fuel are being considered. While this is the only safe attitude for the fuel expert to take, it should be clearly understood that this in no way excludes the due consideration of chemical and by-products questions when these arise as a necessary part of the fuel problem.

*Coke-Ovens.*—So long as the blast furnace remains the instrument for the conversion of iron ore into pig iron, the coke-oven must continue to supply the necessary fuel in the form of hard coke. The "sorting-out process" at the coke-ovens is necessarily coloured by the fact that its primary object is the production of the right kind of coke. So much is this the case that the beehive oven, in which coke is the only product obtained, has only been partially displaced by the recovery oven, in which the by-products, tar, benzol and ammonia, are saved. In the iron and steel industry to-day the most advanced opinion is in favour of the concentration of coke-ovens, blast furnaces, steel furnaces and rolling-mills on one site, so that the whole of the potential heat of the coal may be pooled and used in a closed cycle for the production of heat and power. Mr. Talbot has estimated that in this way the fuel required for the production of one ton of finished steel would be reduced from 45 to 35 cwt. As any general replacement of existing works, under the financial conditions prevalent in 1921, was likely to involve a prohibitive capital cost, a more general use of coke-oven gas for the purposes of town supply was not to be hoped for.

*Carbonisation in Gas-Works.*—In gas-works the sorting-out process is influenced by the fact that the primary purpose is to supply potential light, heat and power in the form of gas. In the British gas industry the fuel problems of the future acquired a new interest after the publication of the report of the Fuel Research Board on the results of their inquiry into the subject of gas standards. The results of this inquiry led to the adoption by the Board of Trade of a new method of charging the consumer for the gas which passes through his meter. The volume of this gas was still measured and recorded, but the consumer no longer paid on thousands of cub. ft. but on the product of the multiplication of the number of cub. ft. passed by the standard calorific value of the gas per cub. foot. The unit of charge was made the "therm," the name adopted for 100,000 British thermal units. Under this system it is now possible to give to the gas undertakings a wide latitude in the selection of the standard of calorific value which they adopt, and therefore a much wider choice of the methods by which gas is manufactured. In the report it was stated that the great gain for the gas undertakings under the new system would be that no undue legislative restrictions would limit them in their development of the most economical production of thermal units in the form of gas. It was pointed out that there was still great scope for this development; as, according to present practice, only from 21 to 24% of the total potential thermal units of the coal was being sold in the form of gas.

To increase this percentage two known methods are available, both depending on the production of water-gas by one or other of the reactions between steam and carbon at a high temperature. The first of these methods is the old-established one in which a portion of the coke produced in the retorts is transferred to a separate producer, in which it is raised to bright incandescence by an air-blast and then subjected to the action of a current of steam. The thermal efficiency of this operation ranges from 45 to 55% according to the method of blowing-up and steaming adopted. The second method has recently been developed in connexion with vertical retorts. In this case the water-gas reactions are carried out in the lower part of the column of red-hot coke in the retort itself, by passing through it a current of steam. The volume of gas produced is much increased, though its calorific value is reduced by the addition of water gas to the hydrocarbon gas resulting from the carbonization of coal.

During 1919–21 continuous experiments were carried out at H.M. Fuel Research Station on the use of steam in vertical retorts with various types of coal. It was proved that, by the use of a moderate percentage of steam, a much larger proportion of the thermal value of the coal can be converted into the fuels of higher availability and value, gas and tar. In the case of a S. Yorkshire coal of good quality the following results were obtained: At a working temperature of 1126°C. and with 21% of steam, the gains per ton of coal were 22 therms in the form of gas, 34 lb. of tar, and 6 lb. of ammonium sulphate. While without steam only 23% of the potential heat of the coal was obtained in the form of gas, with steam 33% was obtained. The extra heat which had to be supplied to the retorts in order to produce these results was ten therms per ton of coal carbonized, or 3·3% of the thermal value of the coal. The gas obtained amounted to 22,580 cub. ft. per ton, with a calorific value of 460 B.Th.U. per cub. foot. Both thermally and economically these results are superior to those which would have resulted from the production of an equivalent

amount of water-gas in separate producers. The independent production of water-gas will always be regarded by gas engineers as an invaluable means by which exceptional demands on the gas supply can be met at short notice.

*Low-Temperature Carbonization.*—For many years inventors have been endeavouring to develop a practical process for the production of a solid smokeless fuel for domestic purposes by the carbonization of selected coals at 550° to 600° C. The resulting coke is entirely free from smoke-producing hydrocarbons, though it still contains 10 to 12% of volatile combustible matter, which burns with a very slightly luminous, perfectly smokeless flame. When the coke is kindled it becomes enveloped by these flames, which quickly raise the surface to incandescence. Undoubtedly if this smokeless solid fuel could be produced at a cost permitting of its being sold at little more than the price of the coal which it would replace, it would lead to a complete revolution in domestic heating.

The problem really has two distinct sides—the technical and the economic. On the economic side the data for a final solution will only be obtained after the technical solution has been reached. In other words, until a fair-sized industrial plant has been worked continuously over a long period, making and disposing of all the products of carbonization under steady market conditions, no one can say whether or not the business will be a profitable one.

On the engineering side an efficient and not too costly apparatus must be designed and constructed in the working of which manual labour, fuel consumption and maintenance costs are all reduced to a minimum. In these respects—as well as in its output capacity on a given ground area—the apparatus must stand comparison with gas retorts and oil-shale retorts of the most modern types. Only when this ideal has been realized practically can the future of low-temperature carbonization as a business proposition be put to the test of continuous working on a large scale under the labour and market conditions of the day.

From the experience gained in 1919–21 at H.M. Fuel Research Station, with a considerable variety of coals, the yields and quality of the gas, oils and coke produced under definite conditions were ascertained; but this knowledge is only the first step in the inquiry. For, until the cost of producing these, and the markets in which they are to be disposed of, are known with equal certainty, no economic balance sheet of any real value can be arrived at. Low-temperature carbonization can only be established on a sound commercial basis with low operating costs and a very moderate margin of profit. Prior to 1914 the shale oil industry in Scotland was distilling three million tons of shale per annum. The entire cost of the carbonizing operation, for labour, maintenance and fuel, was 1s. 6d. per ton, and the margin of profit on which fair dividends were paid was 2s. 6d. per ton. Unless the costs and profit margins of low-temperature carbonization can be reduced to the modern equivalents of these figures, the prospects of its development on a large scale are not hopeful.

If low-temperature carbonization is proved to be a feasible operation commercially, it would find its first and most natural application in Great Britain to the 35 million tons of coal used for domestic purposes. Were this coal all carbonized, it would produce about two million tons of fuel oil for the navy, or considerably more than the peace requirements, though considerably less than the war requirements. The motor spirit produced would amount to about 100 million gallons.

### Conclusions

From this review it appears that coal is likely to remain for a long time the world's chief source of fuel. Its more efficient use may be secured:—(1) by more careful sorting and preparation at the mine; (2) by the improvement of boiler and furnace firing on well-known lines; (3) by the sorting out of its combustible constituents into fuels of higher availability or convenience by preliminary carbonization carried out either at high or at low temperatures. The development of oil shales as a source of liquid fuels was still in 1921 only in its initial stages, but it had evidently a great future before it. The problems of the utilization of peat, which cover a wide range both technically and economically, are mainly of local importance, and are not likely to affect the fuel supplies of the world to any great extent. The production of alcohol on a really large scale as a motor fuel of high availability bristles with economic and technical difficulties, and it was still in 1921 too early to pronounce an opinion on the possibilities of the future. Most, if not all, of these problems on their technical side are probably capable of solution by the skill and application of the industrial pioneers of the world; but the most difficult of the fuel problems of the future, as viewed in 1921, were those into which industrial and economic factors—the relations between capital and labour, and the cost of production—so largely entered. (G. T. B.)

**FURNESS, CHRISTOPHER FURNESS,** 1ST BARON (1852–1912), English shipbuilder and iron-master, was born April 23 1852, the son of a provision merchant, and entered the family business in 1870. By making a corner in food-stuffs, whilst the French fleet was blockading the mouth of the Elbe, he made a profit of over £50,000 for his firm out of the provisioning of ships. In 1877 he left the business and inaugurated the Furness line of steamships, and in 1891 he amalgamated with Withy & Co., iron and steel shipbuilders, founding the great shipbuilding firm of Furness, Withy & Co. at Hartlepool. In 1898, with others, he acquired extensive iron and steel works and founded the S. Durham Steel & Iron Co. He had an interest in many other concerns, and was chief proprietor of a Liberal paper, the *North Mail*. In 1908 he established a profit-sharing scheme for his workmen, but in 1910 its continuance was put to the vote and rejected by a majority. In 1891 he was elected Liberal member for the Hartlepools, but in 1895 he lost the seat, winning it again in 1900. In 1906 he was returned unopposed, and in Jan. 1910 he was elected but unseated on petition. A month later he was raised to the peerage; he had been knighted in 1895. He died at Grantley Hall, near Ripon, Nov. 10 1912.

His nephew, SIR STEPHEN WILSON FURNESS, 1ST BART. (1872–1914), who, after his uncle's death became chairman of the shipbuilding firm and iron and steel works founded by him, as well as of many other undertakings, was born May 26 1872. He sat in the House of Commons for the Hartlepools from 1910, and was made a baronet in 1913. He died at Broadstairs Sept. 2 1914.

**FURNESS, HORACE HOWARD** (1833–1912), American Shakespearean scholar (*see* 11.362), died at Wallingford, Pa., Aug. 13 1912. His *Variorum* edition of *Cymbeline* was ready for the printer and appeared in 1913.

**FURSE, DAME KATHARINE** (1875– ), founder of the English V.A.D. force, was born at Bristol Nov. 23 1875, the daughter of the poet and critic John Addington Symonds (*see* 26.286). In 1900 she married the painter Charles Wellington Furse (*see* 11.365), who died prematurely in 1904. On the outbreak of war in 1914 Mrs. Furse realized that the existing number of nurses would prove totally inadequate to deal with the enormous amount of work which might be expected, and in Sept. 1914 she proceeded to France with a number of assistants, these forming the nucleus of the V.A.D. force (Voluntary Aid Detachment). In Jan. 1915 she returned to England, and the V.A.D. work was then officially recognized as a department of the Red Cross organization. Mrs. Furse resigned her position in 1917, and the same year became director of the W.R.N.S. She received the order of the Royal Red Cross in 1916, and the G.B.E. in 1918

**GAIRDNER, JAMES** (1828–1912), English historian (*see* 11.390*), died at Pinner, Middlesex, Nov. 4 1912. A third volume of his *Lollardy and the Reformation in England* appeared in 1911.

**GALLIÉNI, JOSEPH SIMON** (1849–1916), French general and statesman (*see* 11.418), was appointed military governor of Paris, Aug. 26 1914, and at once took energetic steps for the defence of the capital. Eleventh-hour efforts were made to construct trench defence work and to create modern forts around the capital. On Sept. 3 he issued the following order: "To the Army of Paris and the Population of Paris. The Members of the Government of the Republic have left Paris in order to give a new impulse to national defence. I have been ordered to defend Paris against the invader. This order I shall fulfil to the end." General Galliéni was enabled, owing to information received from his aeroplanes, to hurry out reinforcements to Gen. Maunoury's Army (VI.) during a critical period in the battle of the Ourcq. The Paris taxicabs were requisitioned to transport them. He was appointed Minister of War in the Briand Cabinet at the end of Oct. 1915. His period of office was made notable by endeavours to create unity of command, and by changes in the position of Gen. Joffre. He resigned for reasons of ill-health on March 16 1916, and died at Versailles, after undergoing two operations, on May 27. His body was given a State funeral, and lay for a time under the dome of the Invalides. He lies buried at St. Raphael.

**GALLON, TOM** (1866–1914), British novelist and dramatist, was born in London Dec. 5 1866. He was first a clerk in a city office and then usher in a large private school, but, owing to ill-health, he had to give up routine work, and took to literature as a means of livelihood. He wrote a number of novels in which plot and incident predominate, amongst them *The Kingdom of Hate* (1899); *A Rogue in Love* (1900); and *The Charity Ghost* (1902). He then turned to the writing of plays, collaborating with Albert Chevalier in *Memory's Garden* (1902) and publishing some plays on his own account, *The Christmas Party* (1904); *The Devil's World* (1910) and *The Great Gay Road* (1911). He died in London Nov. 1 1914.

**GALSWORTHY, JOHN** (1867– ), English novelist and playwright, was born at Coombe, Surrey, Aug. 14 1867. He was educated at Harrow and New College, Oxford, and was called to the bar in 1890, but devoted himself mainly to literature. His earliest novel, *Jocelyn*, appeared in 1898; but he first attracted general attention with *The Island Pharisees* (1904) and *The Man of Property* (1906). These were followed by *The Country House* (1907); *Fraternity* (1908); *The Patrician* (1911); *The Dark Flower* (1913); *The Freelands* (1915); *Saint's Progress* (1919); *In Chancery* (1920); *To Let* (1921); in addition to essays and short stories. Meanwhile he had also made a considerable reputation as a writer of realistic drama with a strong emotional appeal, notably *The Silver Box* (1906); *Joy* (1907); *Strife* (1909) and *Justice* (1910). His later plays include *The Pigeon* (1912); *The Eldest Son* (1912); *The Fugitive* (1913) and *The Skin Game* (1920).

See Sheila Kaye-Smith, *John Galsworthy* (1916).

**GALTON, SIR FRANCIS** (1822–1911), English anthropologist (*see* 11.427), died at Haslemere Jan. 17 1911.

**GAMBIA** (*see* 11.437).—The area, reckoning the colony and protectorate together, is 4,132 square miles. At the 1911 census the pop. was 146,101. St. Mary's Isle, at the mouth of the Gambia, on which is Bathurst, the capital, had 7,700 inhabitants (compared with 8,807 in 1901). European residents numbered 186 in 1911 and 112 in 1918. Estimates made in 1920 put the total pop. as high as 240,000.

The cultivation of the ground-nut, the chief occupation of the people, proves so lucrative that the efforts of the administration to widen the basis of prosperity meet with little success, though since 1913 there has been an increased production of food crops, African koos (millet) and rice, for home consumption. The land is all hand-worked, attempts to induce the farmers to adopt modern methods having failed. Up to 1915 the ground-nuts were nearly all purchased by French firms at Bathurst and sent to Marseilles. France in 1914 took 78% of the total crop. Changed conditions created by the World War and the establishment of large oil mills in England led to a diversion of the trade, and in 1916, for the first time for 58 years, Britain received a larger proportion of the crop than was shipped to France. In 1919 Great Britain took 91·44% of the total crop. In that year France took only 2·59%.

Trade in ivory, wax and rubber, formerly considerable, had by 1915 sunk to negligible proportions; besides ground-nuts the chief exports are palm kernels and hides. The restriction of shipping during and after the war caused a contraction of trade; nevertheless the value of exports in the period 1909–19 (excluding specie) rose from £351,000 to £1,229,000. They had dropped to £430,000 in 1915. The rapid recovery was due to increased prices rather than increased production. In 1909 the export of ground-nuts was 53,600 tons, valued at £323,000; in 1918 the export was 56,400 tons and the value £800,000. The most striking contrast was shown in 1914–5. In 1914 the export of ground-nuts was 66,000 tons, fetching £650,000; in 1915 the export was 96,000 tons, but the value fell to £400,000. In 1919 the export was 70,000 tons valued at £1,154,000.

In the period 1909–19 the value of imports, also excluding specie, rose from £258,000 to £1,179,000. In 1915 they had fallen to £302,000. The chief imports are cotton goods, kola-nuts, rice and hardware. Most of the imports come from the United Kingdom but up to 1914 France had a considerable share in the trade (27% in 1913) and Germany a smaller part (10% in 1913). In 1919 France and French possessions supplied only 8% of imports; the United Kingdom over 57%; British possessions 14%; the United States 19%. The American export is mainly rice, sugar and fuel oils. The United States imports rose from £12,000 in 1915 to £235,000 in 1919. America had in that time captured as large a share of the Gambia trade as Germany had had before the World War. It was entirely one-sided, as there were no exports from the Gambia to the United States. The bulk of the imports from British possessions was represented by kola-nuts from Sierra Leone,—valued at £157,000 in 1919.

Shipping is mainly in British hands. Total tonnage rose from 495,000 in 1909 to 625,000 in 1913. In that year British tonnage was 371,000, French 76,000, German 60,000, Greek 33,000. A great restriction followed and in 1918 the total tonnage was only 282,000. Of this total 262,000 tons were British. In 1919 the tonnage entering and clearing at Bathurst was 441,000. Of this 354,000 tons were British, 40,000 American and 19,000 French.

An import duty on kola-nuts and an export duty on ground-nuts are the chief sources of revenue, which rose from £72,000 in 1909 to £180,000 in 1919. In the same period expenditure increased from £56,000 to £143,000. There is no public debt. Education remains in the hands of various Christian missions, except for a Mohammedan school at Bathurst, which is maintained by the Government. For the whole of its length in the protectorate the Gambia is navigable and forms a sufficient means of communication, few places in the protectorate being more than 10 m. from the river. There are neither railways nor inland telegraphs, but there is cable connexion with Europe and other parts of W. Africa, and in 1915 the Admiralty erected a wireless station at Cape St. Mary. By going to Dakar, 90 m. from Bathurst, the passage to Europe by the French packet can be made in eight days.

Since the pacification of the protectorate by Sir George Denton (governor 1901–11) in 1901, the country has been peaceful. The ground-nut industry is entirely in the hands of the natives, who also own large herds of cattle—the symbol of wealth. In 1917 plague carried off fully 75% of the cattle, but as the country was overstocked, many of the cattle being kept simply for show, the effect was not as serious as might have been thought. Much of the petty trade is in the hands of Syrians. In Sept. 1911 Sir H. L. Galway became governor, his tenure of office witnessing a great development of commerce. In April 1914 he was succeeded by Mr. (afterwards Sir) E. J. Cameron, under whose guidance the economic crisis caused by the war (restriction of shipping and consequently of food supplies, with violent fluctuations in the price of ground-nuts) were successfully overcome. During the war the natives gave many proofs of their loyalty to Great Britain, and the Gambia Co. of the West African frontier force served with distinction both in Cameroon and German E. Africa. At the end of 1920 Sir E. J. Cameron retired and was succeeded as governor by Capt. C. H. Armitage, the commissioner of the Northern Territories of the Gold Coast.

See H. F. Reeve, *The Gambia* (London 1912), an excellent monograph by a retired official; Sir G. Denton, "Twenty-three Years in Lagos and the Gambia," *Jnl. African Soc.*, vol. xi. (1912); *The Gambia* (a British Foreign Office handbook, 1920) and the Annual Reports issued by the Colonial Office, London. Full statistics are given in the Blue Book issued yearly at Bathurst. (F. R. C.)

**GANDHI, MOHANDAS KARAMCHAND** (1869– ), Indian political leader, a member of the *bania*, or trading and money-lending caste, was born at Porbandar, in Western India, where his father was for twenty-five years Dewan, or chief minister, of the State. He proceeded to England in 1888 and was called to the bar at the Inner Temple. After practising for eighteen months at Rajkot in Kathiawar, he went to South Africa in 1893. Here he placed himself at the head of the Indian community and organized a campaign of "passive resistance" against various measures of anti-Asiatic legislation. As a result of the inevitable collision with the authorities which ensued he underwent a term of imprisonment. At that time he held that it would be a calamity to sever the connexion between England and India, and during the Boer War he volunteered for service with a corps of Indian stretcher-bearers. In Dec. 1914 he returned to India and in 1916 opened an *asram*, or retreat, at Ahmedabad in the Bombay Presidency. During the lifetime of G. K. Gokhale he remained under his moderating influence; but after his death in Feb. 1915, he became wholly obsessed by the teachings of Tolstoy, to which he had been attached in early life and which he now grafted upon those of the Bhagavadgita. Tolstoy's "letter to a Hindu" (written on Dec. 14 1908) was not actually addressed to him, but it contains all the essential features of the "non-coöperation" agitation which was initiated by him after the passing of the Rowlatt Act in the autumn of 1918, and which was one of the prime factors in the Punjab disturbances of April 1919. The object of *Satyagraha*, or "civil disobedience," which inculcates abstinence from all forms of active association with British rule and an attitude of hostility towards Western civilization in general, is to compel the grant of "swaraj," or full self-government. In Aug. 1920 Mr. Gandhi announced that success would be attained in a year, provided that an "indissoluble union" was brought about between Hindus and Mohammedans and a "conscious voluntary effort" was made by the masses in the matter of treating the "untouchable" castes as "blood brothers" (*Freedom's Battle*, 1921). In neither direction was appreciable progress achieved, although Mr. Gandhi, in order to "buy the friendship" of the Mussulmans "at a critical time in their history" (*ibid.*), identified himself with the extreme wing of the Khilafat movement, which demanded the restoration of the Turkish Empire to the *status quo ante bellum*. Complete failure meanwhile attended a systematic attempt to wreck the first elections held in the autumn of 1920 under the Montagu-Chelmsford reform scheme. Mr. Gandhi's austere asceticism earned for him the title of "Mahatma" and a reputation for the possession of supernatural powers. His own sincerity, it may be noted, was not impugned, but his visionary gospel of "soul force" as opposed to brute force was brought into discredit by the violent and unscrupulous methods adopted by his followers and by the strong anti-British flavour which their propaganda assumed.

See J. J. Doke, *M. K. Gandhi: an Indian patriot in S. Africa* (1909); *Freedom's Battle* (speeches: Madras, 1921). (H. E. A. C.)

**GARDNER, PERCY** (1846– ), English classical archaeologist (*see* 11.462), published subsequently to 1911 *Principles of Greek Art* (1913); *The Ephesian Gospel* (1915); *History of Ancient Courage* (1918); and *Evolution in Christian Ethics* (1918).

His brother, ERNEST ARTHUR GARDNER (1862– ), became during the World War a lieutenant-commander, R.N.V.R., worked in the historical section of the British Foreign Office, and was awarded the gold cross of the Greek Order of the Redeemer in 1918.

**GARFIELD, HARRY AUGUSTUS** (1863– ), American educator, son of James A. Garfield, 20th president of the U.S., was born at Hiram, O., Oct. 11 1863. After graduating from Williams College in 1885, he taught for a year in St. Paul's school, Concord, N.H., and from 1887 to 1903 practised law in Cleveland. He was professor of contracts in the Law school of Western Reserve University from 1891 to 1897; helped to organize, in 1896, the municipal association of Cleveland; and served as president of the Cleveland chamber of commerce, 1908–9. He was professor of politics at Princeton University from 1903 to 1908 and in the latter year became president of Williams College. In Aug. 1917 he was appointed Federal fuel administrator by President Wilson. His duty was to conserve the coal supply and keep the price within reasonable bounds. Local committees were appointed throughout the country to study local conditions and their reports formed the basis for the prices fixed in different localities. The ensuing winter was unusually severe, and serious shortage of coal threatened. This led to his issuing his "idle Mondays" order in Jan. 1918, closing non-essential industries for five consecutive days beginning Jan. 18 and on every Monday thereafter up to March 25. This roused a storm of protest from many manufacturers; and the U.S. Senate voted a resolution, requesting postponement, but this reached him after the order had been signed. On Feb. 14, however, the order was suspended and priority for certain shipments substituted. He disapproved of the method of settling the coal strike in Dec. 1919 and resigned his office, resuming that of president of Williams College.

**GARIBALDI, GIUSEPPE** (1879– ); Italian general, eldest son of Gen. Ricciotti Garibaldi and grandson of the Liberator, was born at Melbourne July 29 1879. He fought under his father in the Greco-Turkish War in 1897, and also served in the South African War. In 1904 he went to Venezuela and fought in the insurrection against President Castro. He was imprisoned and condemned to death, but escaped. In 1905 he was employed in London in making arrangements for the settlement of Italian colonists in Australia. From 1907 to 1909 he worked in the Panama Canal Zone under Goethals, whence he went to Mexico and joined Madero, acting as the latter's chief-of-staff. In 1912 he joined the Greek army to fight in the Balkan wars, and reached the rank of brigadier. In 1914 on the outbreak of the World War he raised an Italian Legion of 14,000 men to fight on the side of France, and his six brothers accompanied him as officers. The Legion fought in the Argonne, and had 6,000 casualties, among the killed being two of the Garibaldi brothers. Giuseppe was made lieutenant-colonel, and subsequently colonel, in the Foreign Legion. In 1915 Garibaldi returned to Italy with his legionaries, and on Italy's entry into the war he and his brothers enlisted as volunteers. They were soon afterwards commissioned, Giuseppe being given command of a battalion. He served with the 4th Army until the spring of 1918, and distinguished himself in command of a regiment, a group of mountain troops and a brigade, and reached the rank of colonel-brigadier. He returned to the French front in March 1918 in command of the famous Brigata Alpi, which formed part of the Italian II. Corps. In June Garibaldi was promoted to brigadier-general, the only Italian officer of reserve to reach this rank. After the Armistice he commanded the Italian 8th Div. in Belgium. He retired from his command in June 1919 and gave up his commission in Feb. of the following year, returning to the business life which had been so often interrupted by these episodes of adventure.

**GARLAND, HAMLIN** (1860– ), American writer, was born at West Salem, Wis., Sept. 16 1860. His father, a farmer, migrated to Iowa, where the boy grew up. He graduated from the Cedar Valley Seminary, Osage, at the age of 21, and taught for a year in Illinois. In 1883 he took up a claim in Dakota, but the following year went to Boston, where he read diligently in the public library and turned to story writing. In 1887 he revisited the scenes of his boyhood, and the drudgery of farm life in the Middle West furnished him with abundant material for his realistic tales. His works include *Main Traveled Roads* (1891); *Prairie Folks* (1892); *A Member of the Third House* (1892); *A Spoil of Office* (1892); *Rose of Dutcher's Coolcy* (1895); *Boy Life on the Prairie* (1899); *Her Mountain Lover* (1901); *The Captain of the Gray Horse Troop* (1902); *The Long Trail* (1907); *Money Magic* (1907); *Cavanagh* (1909); *Other Main Traveled Roads* (1910); *Victor Olnee's Discipline* (1911); *The Forester's*

*Daughter* (1914); *A Son of the Middle Border* (1917) and *A Daughter of the Middle Border* (1921). He was made a member of the American Academy of Arts and Letters in 1918.

**GARSTIN, SIR WILLIAM EDMUND** (1849– ), British engineer, was born in India Jan. 29 1849. Educated at Cheltenham College and King's College, London, he in 1872 entered the Indian Public Works Department. In 1885 he was transferred to Egypt, and in 1892 became Inspector-General of Irrigation in Egypt and Under-Secretary of State for Public Works. He was created K.C.M.G. in 1897 and G.C.M.G. in 1902, and in 1907 was appointed British Government director of the Suez Canal Company. During the World War he was engaged on Red Cross work in England, and was in 1918 created G.B.E.

**GARVICE, CHARLES** (1851–1920), British novelist, was born in London Aug. 24 1851. He was privately educated and began writing early, acting as correspondent for various English and American papers. He produced a volume of poems, *Eve and Other Verses* (1873), and two plays, *The Fisherman's Daughter* and *A Life's Mistake*. It is, however, as a remarkably prolific novelist that he is best known. His first popular successes were made in America, as a writer of serials. Both there and in Great Britain he wrote literally for the million, reproducing again and again the same types and situations, and had the largest circulation on record, as well as a wide circle of correspondents attracted by his books. When told by a friend that his stories were unlikely to live, he pointed to the readers on the seashore with the apt remark, "They are all reading my latest." Amongst his long list of novels may be mentioned: *Just a Girl* (1898); *In Wolf's Clothing* (1908) and *In Cupid's Chains* (1903). He died at Richmond, Surrey, March 1 1920.

**GARVIN, JAMES LOUIS** (1868– ), British journalist, was born at Birkenhead, Ches., April 12 1868, of Irish parentage. When quite young he started journalistic work for the *Newcastle Chronicle* at Newcastle-on-Tyne, and he became a practised leader-writer during his connexion with the staff of that paper from 1891 to 1899. He also contributed to the *Eastern Morning News* at an early period when it was under the editorship of J. A. Spender; and even before 1899, when he joined the editorial staff of the *Daily Telegraph* in London, he had made himself known in well-informed journalistic circles as a brilliant publicist by his contributions to reviews and otherwise, and particularly by numerous articles on foreign affairs as well as domestic politics, mostly under pseudonyms, in the *Fortnightly Review* from 1895 onwards. He became editor of the weekly *Outlook* from 1905 to 1912, and of the evening *Pall Mall Gazette* from 1912 to 1915; and in 1908 he had also become editor of the Sunday *Observer*, which he converted into a great organ of opinion with a much-increased circulation, his association with the *Observer* having in 1921 been maintained continuously during that period. An ardent Imperialist, and intimate supporter of Joseph Chamberlain from the time when the latter became Colonial Secretary in 1895, Mr. Garvin's championship of the Tariff Reform movement in politics was the most powerful in London journalism from 1903 onwards. Deep in the inspiration of Mr. Chamberlain's policy and in the Unionist councils, his influence in this respect was felt throughout the political world, and he contributed largely, by his journalistic work and also by lectures and speeches, to the intellectual side of the policy of the Unionist party, especially as represented by Imperialism and Tariff Reform. In this connexion he published volumes on *Imperial Reciprocity* (1903) and *Tariff or Budget* (1909), and a striking article dealing with the "principles of constructive economics" in the volume of *Compatriot Club Lectures* (1906). With Mr. L. C. M. Amery and others he was one of the founders and chief supporters of the Compatriots' Club, which was started in 1903 to provide intellectual backing for the Tariff Reform policy. After the World War, in the course of which his only son, a young man of brilliant promise, was killed at the front, he published *The Economic Foundations of Peace* (1919), an elaborate plea for reasonable views of reconstruction. In 1920 he was selected to write the official biography of Joseph Chamberlain.

**GARY, ELBERT HENRY** (1846– ), American business man, was born near Wheaton, Ill., Oct. 8 1846. He attended Wheaton College and then after studying law for a time in an office he continued his legal studies at the university of Chicago (LL.B. 1867). In 1871 he began practice in Chicago where he became a noted corporation lawyer. In 1874 he organized the Gary-Wheaton Bank, of which he was president. He was elected judge of Du Page co. in 1882 and again in 1886; was three times elected president of the town of Wheaton and on its becoming a city (1892) served as its first mayor for two terms. He was president of the Chicago Bar Association 1893–4. He early saw the advantages of combination in business and in 1891 was one of the organizers of the Consolidated Steel & Wire Co. In 1898 upon the organization of the Federal Steel Corp., with a capital stock of $200,000,000, he became its head and retired from legal practice. This company was merged in the U.S. Steel Corp. in 1901 and he was elected chairman of the board of directors and of the finance committee. The town of Gary, Ind., laid out in 1906 as a model home for steel workmen, was named in his honour. In 1914 he was made chairman of the committee appointed by Mayor Mitchel, of New York, to study the question of unemployment and its relief. When America entered the World War (1917) he was appointed chairman of the committee on steel of the Council of National Defense. Through his own connexion with a business essential for munitions of war he exerted great influence in bringing about coöperation between the Government and industry. He was interested in strengthening the friendship between America and Japan. In 1919 he was invited by President Wilson to attend the Industrial Conference in Washington, and took a prominent part in it as a firm upholder of the "open shop," of which he was always a strong advocate.

**GASES, ELECTRICAL PROPERTIES OF** (*see* 6.864 for ELECTRIC CONDUCTION THROUGH GASES).—The electrical properties of gases vary greatly with the conditions to which the gas is exposed. A gas in its normal condition is a non-conductor of electricity even though it is the vapour of a good conductor like mercury. On the other hand, when it is exposed to such influences as Röntgen rays, intense electrical forces or the radiation from radioactive substances, it becomes a conductor of electricity. Radioactive radiations are so wide-spread and so difficult to eliminate that it has not been found possible to obtain gases which do not show traces of conductivity under tests as delicate as some of those now at our command. This residual conductivity is, however, so small that we may here leave it out of account.

The most important electrical property of a gas in a normal state is its specific inductive capacity. The significance of this property is best illustrated from the relation $K-1/4\pi = NM$, between the specific inductive capacity $K$, N the number of molecules per unit volume, and M the electrostatic moment which a molecule acquires under unit electric force. As we know N, we can if we know the value of $K$ deduce the value of M, and this will tell us a good deal about the shape and size of the molecule. For example, if we regard the molecules as solid conducting spheres, $M = r^3$ where $r$ is the radius of the sphere. Thus, on this hypothesis we can find the radius of the molecule, if we know the value of $K$, and though the hypothesis itself does not throw much light on the structure of the atom, it is probable that the radius of a conducting sphere which would produce the same electrical moment would be of the same order of magnitude as the linear dimensions of the molecule: the radii of metallic spheres which would give the specific inductive capacities possessed by hydrogen, nitrogen, oxygen and chlorine, are respectively $1{\cdot}19\times10^{-8}$, $1{\cdot}60\times10^{-8}$, $1{\cdot}48\times10^{-8}$, $2{\cdot}04\times10^{-8}$ centimetres. On the more probable hypothesis that the atoms and molecules consist of electrons arranged in equilibrium round centres of positive electricity, the electric force will displace the electrons relatively to the positive centres and thus cause the molecule to have a finite electrical moment. The more rigidly the electrons are connected to the positive charge, the smaller will be this moment and the smaller the specific inductive capacity of the gas.

The values of $K-1$ for the elements belonging to the same

family are connected by a remarkably simple and interesting relation, which was discovered by Mr. Cuthbertson (*Phil. Trans.* A.207, p. 135). It is shown in the following table, where the numbers under the symbols denoting the elements are the values of $\frac{1}{3}(K-1)\times 10^6$:—

| | | | |
|---|---|---|---|
| | | | He |
| | | | $144\times\frac{1}{3}$ |
| N | O | F | Ne |
| 297 | 270 | 192 | 137 |
| P | S | Cl | Ar. |
| 1197 | 1101 | 768 | 568 |
| $=299\times4$ | $=275\times4$ | $=192\times4$ | $=142\times4$ |
| As | Se | Br | Kr. |
| 1550 | 1565 | 1125 | 850 |
| $=258\times6$ | $=261\times6$ | $=187\times6$ | $=142\times6$ |
| | Te | I | X |
| | 2495 | 1920 | 1378 |
| | $=249\times10$ | $=192\times10$ | $=138\times10$ |

Thus the values of $K-1$ for successive elements of the same family—(N.P.As): (O,S,Se,Te): (F.Cl.Br.I): (Ne,Ar,Kr,X)—are in all cases very nearly in the proportion 1, 4, 6, 10. In the simple theory, where the molecules are regarded as conductors, this would indicate that the volumes of the molecules of the successive elements in the same family are in the proportion 1, 4, 6, 10, for each of these types of elements. On the theory which regards the atom as built up of electrons arranged round positive centres, the configuration of the outer layer of electrons for different members of the same family would be similar, and it is easy to show that for similar configurations of electrons the value of $K-1$ would be proportional to the cube of the linear dimensions, *i.e.* to the volume enclosed by the outer layer of electrons; so that again on this theory Cuthbertson's result shows that volumes of successive elements in the same family are in the same ratio whether the family be that of the inert gases, the halogens, or the oxygen or nitrogen groups.

Another example of the information as to the nature of the molecule afforded by determinations of the specific inductive capacity is that, while the specific inductive capacity of many gases, *e.g.* $H_2$, $N_2$, $O_2$, CO, $CO_2$, $Cl_2$, is equal (as Maxwell's Electromagnetic Theory of Light suggests) to the square of the refractive index, there are, as Bädeker (*Zeitschrift Physik. Chem.* 36, p. 305) has shown, others, such as $NH_3$, HCl, $SO_2$, the vapours of water and the alcohols, whose specific inductive capacity is far in excess of the value given by this rule, and moreover the specific inductive capacity of these gases diminishes much more rapidly as the temperature increases than that of gases of the first type. The difference can be accounted for by supposing that the molecules of gases of the first type have no electrical moment when they are free from the action of an external electrical force, while those of the second type have an intrinsic electrical moment apart from that which may be produced by the external force. When there is no electrical field, the collisions between the molecules will cause the axes of electrical moments of the different molecules to be uniformly distributed, so that the average effect will be zero. An electric force will tend to drag the axes of the different molecules into alignment, and the assemblage of molecules will have a finite electrical moment which will be a measure of the specific inductive capacity. Inasmuch as the collisions between the molecules tend to knock their axes out of line and diminish the specific inductive capacity, the latter will diminish as the temperature and with it the vigour of the encounters increases. The substances which have an intrinsic electrical moment have exceptionally active chemical properties and are good solvents, dissociating the salts dissolved in them.

If the distribution of electrons in a molecule were not symmetrical about three axes at right angles to each other, the specific inductive capacity of a single molecule would vary with the direction of the electric force, but as the molecules in a gas are orientated in equal numbers in all directions we should not detect this by direct measurements of the specific inductive capacity. We can however detect this effect in another way; for if the molecules have different specific inductive capacities in different directions the light scattered by the molecules at right angles to the incident unpolarized light will not be plane polarized as it would be if the molecule were symmetrical (J. J. Thomson, *Phil. Mag.* 40, p. 393), and if the incident light is plane polarized the scattered light will not vanish in any direction. Strutt (*Proc. Roy. Soc.* 98A. 57) has measured the departure from plane polarization for different gases with the result shown in the following table:—

| | |
|---|---|
| Argon | 0·46 % |
| Hydrogen | 3·83 % |
| Nitrogen | 4·06 % |
| Air | 5·00 % |
| Oxygen | 9·40 % |
| Carbon dioxide | 11·70 % |
| Nitrous oxide | 15·40 % |

This shows that the molecule of argon is very symmetrical, while the nitrogen molecule is more symmetrical than the oxygen, and this again more symmetrical than that of $CO_2$.

*Ionised Gases.*—Gases may in various ways be put into a state in which they conduct electricity on an altogether different scale from the normal gas. They acquire this conductivity when Röntgen rays or the rays from radioactive substances pass through them, or when they are traversed by cathode or positive rays. Ultra-violet light of very short wave length can impart this property to a gas, while gases recently driven from flames or from near arcs or sparks or bubbled through certain liquids or passed slowly over phosphorus also possess this property.

The conductivity of gases possesses interesting characteristics. In the first place it persists for some time after the agent which made the gas a conductor has ceased to act; it always however diminishes after the agent is removed, in some cases very rapidly, and finally disappears. The conducting gas loses its conductivity if it is sucked through glass-wool, or made to bubble through water. The conductivity may also be removed by making the gas traverse a strong electric field so that a current of electricity passes through it. The removal of the conductivity by filtering the gas through glass-wool or water shows that the conductivity is due to something mixed with the gas which can be removed by filtration, while the removal of the conductivity by the electrical field shows that this something is charged with electricity and moves under the action of the electric force. Since the gas when in the conducting state shows as a whole no charge of electricity, the charges mixed with the gas must be both positive and negative. We conclude that the conductivity of the gas is due to the presence of electrified particles; some of these particles are positively, others negatively, electrified. These electrified particles are called ions, and the process ionization.

The passage of electricity through a conducting gas does not follow the same laws as the flow through metals and liquid electrolytes; in these the current is proportional to the electromotive force, while for gases the relation is represented by a graph like fig. 1, where the ordinates are proportional to the current and

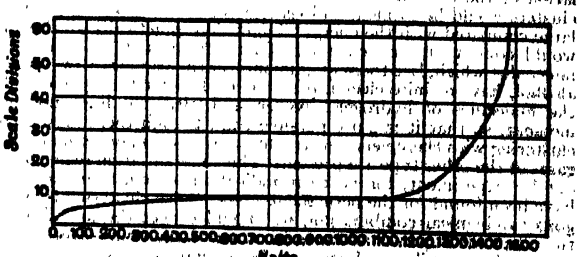

FIG. 1

the abscissæ to the electromotive forces. We see that when the electromotive force is small, the current is proportional to the electromotive force, as in the case of metallic conduction; as the electromotive force increases, the current after a time does not increase nearly so rapidly, and a stage is reached where the current remains constant in spite of the increase in the electromotive force. There is a further stage, which we shall consider later, where the current again increases with the electromotive force, and does so much more rapidly than at any previous stage. The

current in the stage when it does not depend upon the electromotive force is said to be saturated. The reason for this saturation is that the passage of a current of electricity through the gas involves the removal of a number of ions proportional to the quantity of electricity passing through the gas. Thus the gas is losing ions at a rate proportional to the current; it cannot go on losing more ions than are produced, so that the current cannot increase beyond a critical value which is proportional to the rate of production of ions. This sometimes produces a state of things which seems anomalous to those accustomed to look at conduction of electricity exclusively from the point of Ohm's law. For example, when gases are exposed to Röntgen rays, the number of ions produced per second is proportional to the volume of the gas, so that, if two parallel plates are immersed in such a gas and a current sent from one to the other, when the distance between the plates is increased the number of ions available for carrying the current and therefore the saturation current will be increased also. Thus apparent "resistance" will diminish as the length of the gaseous conductor is increased.

*The Nature of the Ions.*—The question arises, what is the nature of the particles which carry the charges of electricity? Are they the atoms or molecules of the gas, or, for the negative charges, electrons? Information on these points is afforded by measuring the velocity of the ions under given electric forces.

It follows from the kinetic theory of gases that the velocity V of an ion due to an electric force X is given by the equation:—

$$V = X\frac{e}{m}\cdot\frac{\lambda}{v} \quad . \quad . \quad . \quad (i)$$

Here $\lambda$ is the mean free path of the ion through the surrounding molecules, $v$ the average velocity of the ion due to its thermal agitation, this velocity depending only on the mass of the ion and the temperature of the gas, and $m$ is the mass of the ion and $e$ the electric charge carried by it. If we calculate by this formula the velocity of an ion in hydrogen, assuming that the mass of the ion and its free path are the same as those for a molecule of hydrogen, we find that it would be 26 cm/sec. for an electric force of a volt per cm.; the value found by experiment is 6·7 cm/sec. for the positive and 7·9 cm/sec. for the negative ion. The assumption that both $\lambda$ and $m$ are the same for the ion as for the molecule is therefore wrong. It is clear that if, as we have every reason to believe, the normal hydrogen molecule is made up of positively and negatively electrified parts, the ion in virtue of its charge, even if its mass is the same as that of the hydrogen molecule, will exert a greater force upon a neighbouring molecule than would an uncharged molecule, and this increase in the force implies a diminution in the free path, and therefore by equation (i) a diminution in V. That a part of the discrepancy between the results given by the equation and those found by experiment is due to this cause cannot be questioned; the point which is still doubtful is whether the attraction due to the charge on the ion may not cause some of the hydrogen molecules to cling to it, forming a cluster of molecules with a greater mass and smaller free path than a single molecule. It would follow from the general principles of thermodynamics that, if the work required to separate a neutral molecule of hydrogen from a positive charge in its near neighbourhood were comparable with the average energy of translation of the molecules at the temperature of the gas, some such clusters would be formed, and that, if the work of separation were large compared with the energy of agitation, practically all the ions would consist of such clusters. This work would be greater for molecules which, like those of ammonia, or the vapours of water and alcohol, have a finite electrical moment, than for those which, like the molecules of hydrogen, oxygen and nitrogen, have no such moment, so that it is quite possible that, though there may be no clustering with these very permanent gases, there may be some when gases of the other type are present. This differentiation seems borne out by experiment, for no clear indications of clustering seem to have been found for the permanent gases. Since clustering is analogous to chemical combination, we should expect the mobilities, if they depended upon clusters, to have very large temperature coefficients. The mobilities of some of the permanent gases at constant density have been measured by Erikson over a considerable range of temperature, and though there is a considerable temperature effect it is not nearly so large as we should expect if it depended on chemical combination. Again, since clustering is a process of condensation, it would be favoured by an increase in pressure; thus a decrease in pressure would be accompanied by a simplification of the ion, and would increase its mean free path beyond the natural increase due to the diminution in the number of molecules with which the ion comes into collision. If there were no change in the character of the ion with the pressure, the mobility would vary inversely as the pressure; if the character of the ion changes, the mobility at low pressures will be greater than that given by this law. Now experiments show that for the positive ion the mobility is, very accurately, inversely proportional to the pressure over a wide range of pressures; this again is inconsistent with the existence of clusters. On the other hand, it is found that the addition of small quantities of gases which, like the vapours of water and alcohol, have a finite electrical moment produce a marked diminution in the mobility; this effect is more pronounced for the negative than for the positive ion, but as Zeleny has shown it exists for both ions. This effect is readily explained by supposing the water molecules to cluster round the ion. It would seem in accordance with the evidence to conclude that, though there is no evidence of clustering for the permanent gases, it does occur when certain easily condensible gases are present.

The behaviour of negative ions is in many respects quite different from that of the positive ones. In the first place the mobility of the negative ions is for the permanent gases greater than that of the positive; thus, for example, in dry hydrogen the velocities of the negative and positive ions, when the electric force is one volt per cm., are 7·95 and 6·7 respectively, and for air 1·87 and 1·36. The difference is less for moist gases than for dry, while for complex vapours which have comparatively small mobilities Wellisch found that there was very little difference between the mobilities of the positive and negative ions.

For the permanent gases the ratio of the mobilities of the negative and positive ions varies but little with the pressure, until the pressure is reduced below that represented by about 10 cm. of mercury. For lower pressures than this, the mobility of the negative ion increases, as Langevin showed, more rapidly than that of the positive; at the pressure of a mm. or so the mobility of the negative ion in air may be three or four times that of the positive.

An even more interesting result was discovered by Franck and Hertz, who, when they experimented with very carefully purified nitrogen or argon, found that the mobility of the negative ion was more than 100 times that of the positive. The mobilities in these gases are extremely sensitive to traces of oxygen, and a fraction of 1% of oxygen added to the pure gas will reduce the mobility of the negative ion to less than one-tenth of its maximum value. The enormous mobility of the negative ion in nitrogen and argon as compared with that of the positive shows that in them the negative electricity must be carried by electrons and not by atoms or molecules, while the effect of introducing traces of oxygen shows that these electrons readily attach themselves to the molecules of oxygen though they are unable to adhere to molecules of nitrogen or argon. The same effect has also been observed in helium and hydrogen.

These properties of the negative ion are of great importance in connexion with the mechanism of ionization in gases and the structure of atoms and molecules. In the first place, they furnish strong evidence in support of the view that the first stage in the ionization of a gas is the ejection of an electron from the molecule of the gas rather than the separation of the molecule into atoms of which some are charged with positive and others with negative electricity. On this view the negative ion begins its career as an electron and not as an atom, while the positive ion from the beginning is of molecular dimensions. As an electron has much greater mobility than a molecule the mobility of the negative ion will at first be much greater than that of the positive. In some gases, such as oxygen, the electron soon gets attached to a molecule, and its mass and mobility become comparable with those of the positive one. The mobility we measure is the average mobility of the negative ion during its life; part of the time its mobility, being that of an electron, is very much larger than that of the positive ion, while in the other part the two mobilities will be much the same. The excess of mobility of the negative over the positive ion will depend upon the fraction of its life which the negative ion spends as a free electron—a fraction which would tend to increase as the pressure of the gas diminished.

To calculate the mobility of an electron as compared with that of a molecule, we must make some assumption as to the effect of the charge on the mean free path of an electron. We saw that there were some grounds for supposing that, in the case of the positive ions, the mean free path was determined rather by the charge of the ion than by the dimensions of the molecule carrying the charge. Since the magnitude of the charge on the electron is the same as that on the positive ion, we might expect, if this were the case, that the mean free path of an electron would be much the same as that of an ion, so that in equation (i) it would be the factor $mv$ which would differentiate the mobility of the ion from that of the electron. If the electron is in thermal equilibrium with the surrounding gas, $mv^2$ will be the same for the ion and the electron, and thus the mobility will be inversely proportional to the square root of the mass; as the mass of the hydrogen molecule is $3{\cdot}6\times10^4$ times that of the electron, the mobility of the electron in hydrogen should be 60 times that of the positive ion; in nitrogen the mobility of the electron would be about 220 times that of the positive ion. If the positive ion were a cluster of molecules instead of a single molecule, the mobility of the electron as compared with that of the positive electron would be much larger than the preceding figures would indicate.

The difference between the behaviour of the electron in nitrogen or argon and in oxygen is of great importance in connexion with the structure of the atom and molecule, for it indicates that, while a molecule of oxygen can accommodate another electron in addition to those already present, the molecules of nitrogen and argon are

unable to do so. It is instructive therefore to consider the results in connexion with the power of the atoms and molecules of the different elements to acquire a negative charge obtained by the study of the positive rays. These show that, while the atoms of hydrogen, carbon, oxygen, fluorine or chlorine readily acquire a negative charge, those of helium, nitrogen, neon, and argon do not; and again that, while it is very exceptional for a molecule whether of a compound or an elementary gas to acquire a negative charge, the molecule of oxygen is able to do so. We see that this result is in accordance with the behaviour of the carrier of the negative charge in an ionized gas. Since the atoms in the positive rays show so much greater affinity for the electrons than the molecules, it follows that if the agent producing ionization were to dissociate some of the molecules of the gas into neutral atoms (and to do this would require the expenditure of much less energy than to ionize the gas), these atoms would be much more effective traps for the electrons than the undissociated molecules. Loeb has shown that even in oxygen an electron collides on the average with about 50,000 molecules of oxygen before it is captured; thus if the oxygen *atom* could capture an electron at the first encounter, if only one molecule in 50,000 were dissociated into atoms, the effect of the atoms would be as efficacious as that of the molecules in capturing the electrons. When this dissociation takes place the abnormal velocity of the negative ion will only occur in gases like nitrogen and the inert gases whose *atoms* cannot receive an electron.

*Recombination of the Ions.*—Even when the ions are not removed from a gas by sending a current of electricity through it, their number will not increase indefinitely with the time of exposure of the gas to the ionizing agent. This is due to the recombination which takes place between the positive and negative ions; these ions as they move about in the gas sometimes come into collision with each other, and by forming electrically neutral systems cease to act as ions. The gas will reach a steady state with regard to ionization when the number of ions which disappear in one second as the result of the collisions is equal to the number produced in the same time by the ionizing agent.

If there are $n$ ions of either kind per cub. cm., the number of collisions between the positive and negative ions in one second in a cub. cm. of the gas will be proportional to $n^2$; hence the number of ions of either sign which are lost by recombination in one second will be represented by $an^2$ when $a$ is called the coefficient of recombination. If the ionizing agent produces $q$ ions per cub. cm. per second, then—

$$\frac{dn}{dt} = q - an^2.$$

The solution of this equation, if we reckon $t$ from the instant the ionizing agent begins to act, so that $n=0$ when $t=0$, and where $K^2 = q/a$, is—

$$n = K(e^{2Kat} - 1)/(e^{2Kat} + 1)$$

We see that, when the gas reaches a steady state, $n = K = \sqrt{q/a}$, and that the gas will not approximate to this state until $t$ is large compared with $\frac{1}{2}Ka$, *i.e.* to $\frac{1}{2}n_0 a$ where $n_0$ is the value of $n$ in the steady state. Thus when the ionization is very weak it may take a considerable time for the gas to reach a steady state.

When the ionizing agent is removed, the ions do not disappear at once, but decay at the rate given by the equation—

$$\frac{dn}{dt} = -an^2.$$

The solution of this, where $t$ is the time which has elapsed since the removal of the ionizing agents, and $n_0$ the number of ions when $t=0$, is—

$$n = n_0/(1 + n_0 at).$$

Thus the number of ions will be reduced to one-half their initial value after a time $1/an_0$. We may therefore take $1/an$ as the measure of the life of an ion when there are $n$ ions per cub. centimetre. The values of $a/e$, where $e$ is the charge on an ion, have been measured by various experimenters, and for different methods of ionization the results are given in the following table:—

*Values of $a/e$ for various gases at atmospheric pressure and ordinary temperature.*

| | Townsend | McClung | Langevin | Thirkill | Henderen | Retschinsky | Rumelin | |
|---|---|---|---|---|---|---|---|---|
| Gas | Röntgen rays | Röntgen rays | Röntgen rays | Röntgen rays | $\alpha$ rays | $\alpha$ rays | $\alpha$ rays | $\beta$ rays |
| Air | 3420 | 3380 | 8200 | 3580 | 3300 | 4200 | 4240 | 5820 |
| $CO_2$ | 3520 | 3490 | 3400 | 3590 | .. | .. | .. | .. |
| $H_2$ | 3020 | 2940 | .. | .. | .. | .. | .. | .. |
| $O_2$ | 3380 | .. | .. | .. | .. | .. | .. | .. |
| $SO_2$ | .. | .. | .. | 3000 | .. | .. | .. | .. |
| $N_2O$ | .. | .. | .. | 2960 | .. | .. | .. | .. |
| CO | .. | .. | .. | 1780 | .. | .. | .. | .. |

The results as ascribed to Thirkill were obtained by extrapolation from experiment made at lower pressures. Since $a$, in electrostatic measure, is $4{\cdot}8\times10^{-10}$, the value of $a$ for air is about $1{\cdot}6\times10^{-9}$, so that, when there are $n$ positive and $n$ negative ions per cub. cm., the number of ions which recombine per second is—

$$1{\cdot}6\times10^{-9}n^2.$$

This shows very markedly the influence of the electric charge in increasing the number of collisions between the particles, for the number of collisions in a second between $2n$, uncharged molecules in a cub. cm. of air is only—

$$4\times10^{-10}n^2,$$

which is only about 1/4,000 of the number of recombinations between the same number of ions.

It is a very remarkable fact, and one which has not yet received a satisfactory explanation, that the values of $a$ for gases of such different molecular weights as $H_2$, $O_2$, $CO_2$, $SO_2$ should be so nearly equal, while the value of $a$ for CO is only about one-half of that for the other gases.

For pressures less than one atmosphere Thirkill has shown that $a$ diminishes as the pressure $p$ diminishes, and that the relation between $a$ and $p$ is a linear one. Langevin showed that $a$ for air attained a maximum value at a pressure about two atmospheres, and that at higher pressures it diminished somewhat rapidly as the pressure increased.

When the density is constant the value of $a$ diminishes as the temperature increases. The connexion between $a$ and the absolute temperature T seems to be expressed with fair accuracy by the equation—

$$a = cT^{-n}.$$

According to Erikson, $n$ is equal to 2·3, 2·42, 2·35 for hydrogen, air and $CO_2$ respectively, while Phillips' experiments gave $n=2$.

*Large Ions.*—The ions we have been considering are those produced in dust-free gases by Röntgen or cathode rays. In some cases, however, ions with very much lower mobilities are to be found in gases. Thus Langevin found in air from the top of the Eiffel Tower two types of ions, one consisting of ions of the kind we have been considering, with a mobility of about 1·5 cm/sec., the other of ions with a mobility of 1/3,000 cm/sec. Ions with mobilities of the same order as this second type may be produced by bubbling air through water, by passing air over phosphorus, or by drawing air from the neighbourhood of flames. They are probably charged particles of dust of various kinds, held in suspension in gas which is exposed to some kind of ionizing agent which gives a supply of ions of the first type; these settle on the particles of dust and form the slow ions. The number of these slow ions when the gas is in a steady state will only depend on the number of dust particles in the gas, and will not be affected by the strength of the ionizing agent. This follows from the principle that in the steady state the number of dust particles which acquire a positive charge must equal the number which lose such a charge. A positively electrified dust particle might lose its charge by meeting and coalescing with a negative small ion or by coalescing with a negatively electrified dust particle. These dust particles are, however, so sluggish in their movements that, unless the dust particles are enormously more numerous than the small ions, we may neglect the second source of loss in comparison with the first.

Thus if U is the number of uncharged dust particles in a cub. cm. of the gas, P and N the number of those with positive and negative charges respectively, and $p$, $n$ the number of positive and negative small ions, the number of dust particles which acquire per second a positive charge will be $\alpha U p$ and the number losing such a charge by coalescing with a negative ion $\beta P n$, where $\alpha$ and $\beta$ are constants; hence for equilibrium—

$$\alpha U p = \beta P n.$$

Similarly by considering the negatively charged particles we get—

$$\alpha' U n = \beta' N p.$$

Hence we see that the proportion between the charged and uncharged particles of dust depends only upon the ratio of $p$ to $n$, and not upon the absolute magnitude of either of these quantities. Thus, though it would take much longer to reach the steady state with a feeble source of ionization than with a strong one, when that state was reached there would be as much dust electrified in one case as in the other. De Broglie estimates that in this state about one-tenth of the particles would be electrified.

*Relation between the Potential Difference and the Current through an Ionized Gas.*—We shall take the case of two infinite parallel metal plates maintained at different potentials and immersed in an ionized gas; the line at right angles to these plates we shall take as the axis of $x$, it being evidently parallel to the direction of the electric force X. Let $n_1$, $n_2$ be respectively the number of positive and negative

ions at the place fixed by the coördinate $x$; $u_1$ and $u_2$ the velocities of these ions. The volume density of the electrification in the gas, if it is entirely due to the ions, is $(n_1-n_2)e$ when $e$ is the charge on an ion, hence—

$$\frac{dX}{dx}=4\pi(n_1-n_2)e \quad . \quad . \quad . \quad (1).$$

If $\iota$ is the current through unit area of the gas—

$$\iota=e(n_1u_1+n_2u_2) \quad . \quad . \quad . \quad (2).$$

Hence from (1) and (2) we have—

$$n_1e=\frac{\iota}{u_1+u_2}+\frac{1}{4\pi}\frac{u_2}{u_1+u_2}\frac{dX}{dx} \quad . \quad . \quad . \quad (3),$$

$$n_2e=\frac{\iota}{u_1+u_2}-\frac{1}{4\pi}\frac{u_1}{u_1+u_2}\frac{dX}{dx} \quad . \quad . \quad . \quad (4).$$

When things are in a steady state, neglecting any loss of ions by diffusion we have—

$$\frac{d}{dx}(n_1u_1)=q-an_1n_2 \quad . \quad . \quad . \quad (5),$$

$$-\frac{d}{dx}(n_2u_2)=q-an_1n_2 \quad . \quad . \quad . \quad (6),$$

where $q$ is the number of ions produced per second in a cub. cm. of gas, and $a$ is the coefficient of recombination; if $K_1$, $K_2$ are the mobilities of the positive and negative ions respectively, then—

$$u_1=K_1X, \qquad u_2=K_2X.$$

From equations (1), (5) and (6) we get—

$$\frac{d^2X^2}{dx^2}=8\pi e(q-an_1n_2)\left(\frac{1}{K_1}+\frac{1}{K_2}\right),$$

and, substituting the values of $n_1$ and $n_2$, we get—

$$\frac{d^2X}{dx^2}=8\pi e\left(\frac{1}{K_1}+\frac{1}{K_2}\right)\left\{q-\frac{a}{e^2X^2(K_1+K_2)^2}\left(\iota+\frac{K_2}{8\pi}\frac{dX^2}{dx}\right)\left(\iota-\frac{K_1}{8\pi}\frac{dX^2}{dx}\right)\right\} \quad . \quad . \quad . \quad (7).$$

No general solution of this equation has been obtained, but when $\iota$ is small compared with the saturation current $qle$, an approximate solution is represented by the graph in fig. 2.

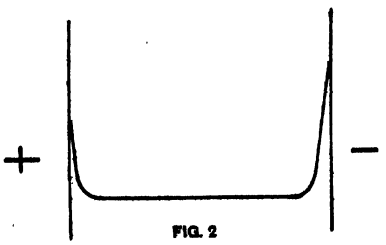

FIG. 2

The force is practically constant, and equal to—

$$\left(\frac{a}{q}\right)^{\frac{1}{2}}\frac{\iota}{e(K_1+K_2)},$$

except close to the electrode, where it increases; and as the mobility of the negative ion is greater than that of the positive the increase in the force will be greater at the cathode than at the anode. As the potential difference between the electrodes increases, and the current approaches more nearly the saturation value, the flat part of the graph diminishes, and the graph for X takes the form given in fig. 3. When the potential difference is so large that the current is

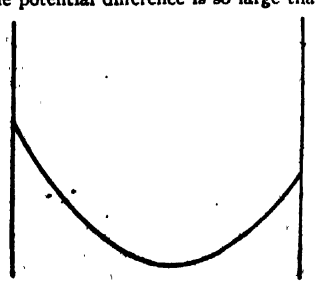

FIG. 3

nearly saturated, X is very approximately constant from one electrode to another.

In one extremely important case, that in which the negative ions are electrons and have a mobility which may be regarded as infinite in comparison with that of the positive ions, equation (7) admits of integration: for by putting $K_1/K_2=0$ in equation (8) it becomes—

$$\frac{dX^2}{dx}+\frac{8\pi e^2K_2qX^2}{a\iota}=\frac{8\pi\iota}{K_2}.$$

If, as is more convenient in this case, $x$ is the distance from the cathode instead of from the anode, as we have hitherto assumed, the solution of this equation is—

$$X^2=\frac{a\iota^2}{qK_2^2e^2}+Ce^{\frac{-8\pi e^2K_2qx}{a\iota}} \quad . \quad . \quad . \quad (9).$$

The second term on the right-hand side diminishes very rapidly as $x$ increases and soon gets negligible, so that we see that the electric force will be constant except in the immediate neighbourhood of the cathode. To find the value close to the cathode we must find the value of C in equation (9). We have from equation (7)—

$$\left[\frac{1}{8\pi e}\frac{dX^2}{dx}\frac{K_1K_2}{(K_1+K_2)}\right]_0^{x_1}=\int_0^{x_1}(q-an_1n_2)dx \quad . \quad . \quad . \quad (10).$$

The right-hand side of this equation is the excess of ionization over recombination in the region between the cathode and $x$; it must therefore be equal to the excess of number of the negative ions passing through the gas at $x$; it must therefore be equal to $(\iota-\iota_0)/e$ where $\iota_0$ is the amount of negative electricity emitted by unit area of the cathode in unit time. Putting this value for the right-hand side of equation (10) we find approximately, since $K_1$ is small compared with $K_2$,—

$$C=\frac{a\iota}{qK_1K_2}\frac{(\iota-\iota_0)}{}\frac{K_1+K_2}{K_2}=\frac{a\iota(\iota-\iota_0)}{qK_1K_2}.$$

Substituting this value for C, we find—

$$X^2=\frac{a\iota^2}{qK_2^2e^2}\left(1+\frac{K_2}{K_1}\frac{\iota-\iota_0}{\iota}e^{\frac{-8\pi e^2K_2qx}{a\iota}}\right) \quad . \quad . \quad . \quad (11)$$

This distribution of force is represented by the graph in fig. 4; the force at some distance from the cathode is equal to—

$$\frac{\iota}{Ke}\left(\frac{a}{q}\right)^{\frac{1}{2}},$$

and is thus proportional to the current; the force at the cathode itself is $\{K_2(\iota-\iota_0)/K_1\iota\}^{\frac{1}{2}}$ times greater than this. The fall of potential between the electrodes is made up of two parts, one arising from the constant force; as this force is proportional to $\iota$, this part of the potential fall will be proportional to $l$ when $l$ is the distance between the electrodes, and may be represented by $Al$ when A is a constant; the other part of the potential fall is that which occurs close to the cathode. We find from equation (11) that this is proportional to $\iota^{\frac{1}{2}}$

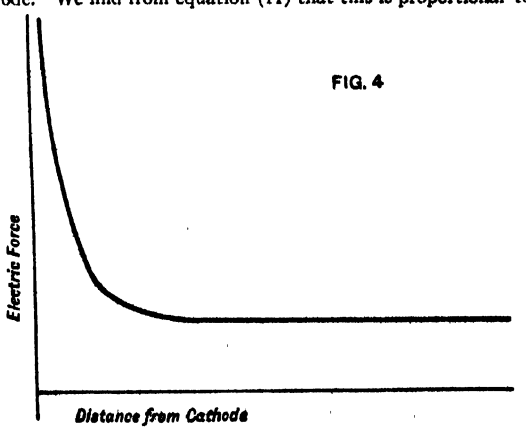

FIG. 4

and does not depend upon $l$. Thus, if V is the potential difference between the electrodes when A and B are constants—

$$V=Al+B\iota^{\frac{1}{2}} \quad . \quad . \quad . \quad (12).$$

H. A. Wilson has shown that an equation of this type represents the relation between the current and potential difference for conduction through flames. In many cases the drop of potential at the cathode is much greater than the fall in the rest of the circuit; when this is so we see that the current is proportional to the square root of the potential difference. The value of B increases with the pressure and decreases with the amount of the ionization.

*Current from Hot Wires.*—A case of great importance from its industrial application in hot wire valves is one where all the ions are negative and are emitted from the cathode. Metal wires raised to incandescence emit electrons, and if they are used as cathodes can transmit across a vacuum or gas at a low pressure very considerable currents. No currents will pass if they are used as anodes.

Take the hot cathode as the origin from which $x$ is measured; let V be the potential at the point $x$, $n$ the density of the negative ions at this point, and $\iota$ the current through unit area. If $a$ is the velocity of the negative ion, we have

$$nue=\iota \text{ and } \frac{d^2V}{dx^2}=4\pi ne.$$

There are two cases to be considered; the first is when the hot wire is surrounded by gas of sufficient density to make the velocity

of the ions proportional to the electric force; the second is when the hot wire is surrounded by a vacuum, and the motion of the ions is not affected by the gas.

In the first case $u = K_3 \frac{dV}{dx}$, when $K_3$ is the mobility of the negative ion, and the equation $nue = \iota$ is equivalent to—

$$\frac{K_3}{4\pi} \frac{dV}{dx} \frac{d^2V}{dx^2} = \iota \quad . \quad . \quad . \quad (13).$$

The solution of this is—

$$\left(\frac{dV}{dx}\right)^2 = \frac{8\pi\iota}{K_3} x + C.$$

Therefore if V is the difference of potential between the anode and cathode, and $l$ the distance between them,—

$$V = \frac{K}{12\pi\iota}\left[\left(\frac{8\pi l}{K} + C\right)^{\frac{3}{2}} - C^{\frac{3}{2}}\right] \quad . \quad . \quad . \quad (14).$$

If $u_0$ is the velocity of the negative ions at the cathode, $\iota = ne u_0$; hence

$$\frac{\iota}{I - \iota} = \frac{\sqrt{6\pi u_0}}{c} \quad . \quad . \quad . \quad (15).$$

So that, unless $\iota$ is small compared with I, $u_0$ will be comparable with $c$; in this case, however, the velocity of the ion is no longer proportional to the electric force so that equation (13) no longer holds. Again, when the current approaches saturation, $\iota/(I-c)$ is large, and therefore by (15) $u_0$ will be large compared with $c$. For the negative ion to acquire a velocity of this magnitude the electric field would have to be so strong that sparks would pass through the gas unless the pressure were very low. Thus saturation currents from hot bodies are only obtainable at very low pressures.

Since $u_0 = K\sqrt{C}$, $\quad C = \frac{c^2}{6\pi K^2} \frac{\iota^2}{(I-\iota)^2}$

Comparing this with the value of $8\pi l/K$ we find, by substituting the values of $K$ and $c$, that if the current is far from saturation, C will be negligible compared with $8\pi l/K$, unless $Il$, when $l$ is measured in centimetres and I in milliamperes, is small compared with unity. When C can be neglected, equation (12) gives—

$$\iota = \frac{qK}{32\pi} \frac{V^2}{l^3} \quad . \quad . \quad . \quad (16).$$

Thus the current is proportional to the square of the potential difference. A remarkable thing about this expression is that for these very small currents the intensity of the current is independent of the temperature of the wire, although, of course, the range of currents over which this formula is applicable is wider the higher the temperature of the wire.

When the hot body is in a vacuum, we have, if the ions have no initial velocity,—

$$\tfrac{1}{2}mu^2 = Ve,$$

where $m$ is the mass and $e$ the charge on an ion; hence the equation $nue = \iota$ is equivalent to—

$$\frac{d^2V}{dx^2} V^{\frac{1}{2}} = 4\pi\iota\sqrt{m/2e} \quad . \quad . \quad . \quad (17),$$

a solution of which is

$$V = (9\pi\iota)^{\frac{2}{3}} (m/2e)^{\frac{1}{3}} x^{\frac{4}{3}} \quad . \quad . \quad . \quad (18).$$

Hence, if V is the potential difference and $l$ the distance between the electrodes—

$$\iota = \frac{1}{9\pi l^2}\left(\frac{2e}{m}\right)^{\frac{1}{2}} V^{\frac{3}{2}}$$

We see from this equation that the electric force vanishes at the cathode, and that the density of the negative electrification is proportional to $x^{-\frac{1}{2}}$; thus it is infinite close to the cathode and diminishes as the distance from the anode diminishes. The total quantity of electricity between the anode and cathode is proportional to $l^{\frac{1}{2}}$. We see again that for a given potential difference the current does not depend on the temperature of the hot wire; this law only holds when the currents are less than the maximum currents which can pass between the electrodes. When the current approaches this value, the current instead of increasing as $V^{\frac{3}{2}}$ becomes independent of V and the negative electricity between the electrodes diminishes as V increases. Langmuir, who has made a very complete investigation of the currents from hot wires, finds that the expression (7) represents, with considerable accuracy, the relation between the current and potential over a wide range in the values of the currents. The curves in fig. 5 given by him represent the relation between the current and potential for wires at different temperatures. They illustrate the point that a colder wire, until it is approaching the stage of saturation, gives as large a current as a hotter one, though the hotter one, of course, has a wider range of currents.

*Ionisation by Collision.*—The curve representing the relation between the currents through a gas ionized (say) by Röntgen rays and the difference of potential between the electrodes is found to be of the form already shown in fig. 1, where the ordinates represent the currents and the abscissæ the potential difference. The flat part represents the state of saturation when the potential difference is large enough to send all the ions produced by the rays to the electrode before they can recombine. When the potential difference is still further increased we see that a stage is

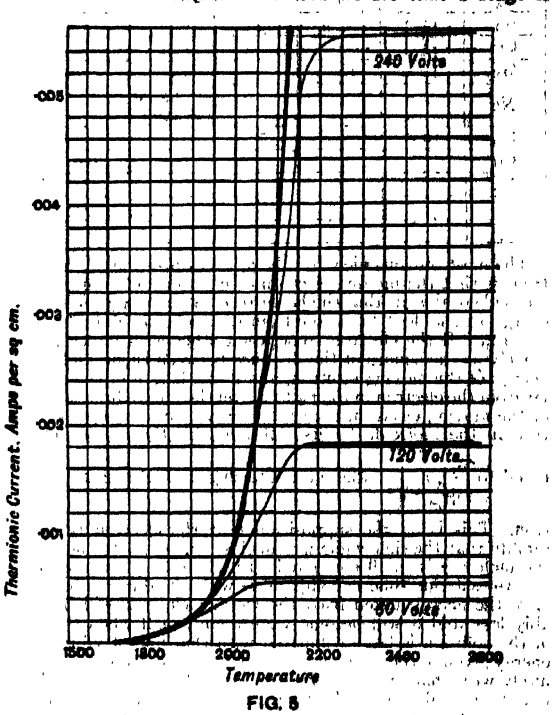

FIG. 5

reached when the current begins to increase with great rapidity with the potential difference, and reaches values much greater than could be attained by the ions produced by the Röntgen rays. Thus in addition to the ions produced by the rays there must be other ions, and some other source of ionization associated with the strong electric fields. Now the processes going on in a gas while it is conveying an electric current are:—(1) the ionisation of the gas by the external agent—in this an electron is liberated from the molecule and the residue forms a positive ion; (2) the electron and the positive ion acquire energy under the action of the electric forces; (3) in many gases the electron finally unites with an uncharged molecule to form a negative ion. As the most noticeable change in the conditions when the intensity of the electric field increases is in the energy of the electrons and ions, it is natural to look to these as the source of the additional ionisation. We have moreover direct experimental evidence that rapidly moving electrons and ions are able to ionize a gas through which they are passing. Hot wires and metals exposed to ultra-violet light yield a supply of electrons which when they leave the metal have very little energy; by applying suitable electric fields these electrons can be endowed with definite amounts of energy and can then be sent through a gas from which all extraneous ionizing agencies are shielded off. When this is done it is found that, when the energy of the electrons exceeds a certain critical value, depending upon the nature of the gas, the gas is ionized by the electrons, but no ionization occurs when the energy of the electron falls below this limit. It is convenient to measure the energy of the electron in terms of the difference of electrical potential through which the electron has to fall in order to acquire this energy. The potential difference which would give to the electron the energy at which it begins to ionize the gas is called the ionising potential. The values of the ionizing potential have been found for several gases, as will be seen from the following table. There is, however, considerable discrepancy between the results obtained by different observers.

*Ionizing Potentials.*

| Gas | Stead & Gosling | Franck & Hertz | Davis & Goucher | Horton & Davis | Tate & Foote | Hughes & Dixon |
|---|---|---|---|---|---|---|
| $H_2$ | 15 | 11 | 11 and 15 | | | 10·2 |
| He | 20·8 | 20·5 | | 25·6 | | |
| $O_2$ | | 9 | | | | 9·2 |
| $N_2$ | 17·2 | 7·5 | 17 | | | 7·7 |
| CO | 15 | | | | | 7·2 |
| Arg. | 12·5 | 12 | | 15 | | |
| Ne | | | | 16·7 & 20 & 22·8 | | |
| Hg | 10·8 | | | | | 10·2 |
| Cd | | | | | 8·9 | |
| Na | | | | | 5·1 | |
| K | | | | | 4·1 | |
| Zn | | | | | 9·5 | |

The most obvious view to take of this ionization by moving electrons is that the moving electron comes so near to an electron in a molecule of the gas that the latter receives from the collision enough energy to enable it to escape from the molecule and start as a free electron. If the electrons repel each other with forces varying inversely as the square of the distance between them, and if T is the energy of the moving electron, and $d$ the length of the perpendicular from the electron in the molecule on the initial direction of motion of the moving electron, then the energy communicated to the electron in the molecule by its collision with the moving electron is equal to $\frac{T}{1+\frac{d^2}{e^4}T^2}$, where $e$ is the charge of electricity on an electron. This is on the supposition that the electron is moving so rapidly that the time while it is in close proximity to the electron in the molecule is small compared with the time of vibration of that electron; if this time is comparable with the duration of the collision, the energy taken from the moving electron will be considerably less, and it will become vanishingly small when the duration of the collision is large compared with the time of vibration. The energy given to the electron in the molecule does not increase indefinitely with that of the moving molecule, for it vanishes when T is infinite as well as when T is zero; it has the maximum value when $T=e^2/d$. In order that the electron in the molecule should receive an amount of energy Q,—

$$Q=\frac{T}{1+\frac{d^2}{e^4}T^2}, \text{ or } d^2=\frac{e^4(T/Q-1)}{T^2}.$$

If Q is the ionizing potential, $d^2$ must be less than the value given by this expression. If $n$ is the number of *electrons* in unit volume of the gas, and if the spheres with radius $d$ described round the different electrons do not overlap, the probability that the moving electrons should come within this distance of one of them, when moving through a distance $\Delta x$, is $n\pi d^2\Delta x$, or

$$\frac{n\pi e^4(T/Q-1)}{T^2}.$$

The coefficient of $\Delta x$ is the number of ions made per unit path by a moving electron with energy T. The maximum is when $T=2Q$.

Experiments on ionization by moving electrons have been made by Kössel (*Ann. der Phys.* 37, p. 406) and by Mayer (*ibid.* 45, p. 1), who found that the maximum ionization per unit path occurred when the energy of the moving electron was in the neighbourhood of 200 volts. Mayer's results are 125 for hydrogen, 130 for air, and 140 for carbon dioxide. These numbers are much greater than twice the potential at which the ionization begins, as this potential is of the order of 11 volts. It must be remembered, however, that, though there may be some electrons in the atom which can be ejected by 11 volt electrons, there may be other electrons of different types which require more energy for their expulsion, so that, as the energy of the moving electrons increases beyond the energy required to liberate these electrons, fresh sources of detachable electrons will be trapped, and these may more than counterbalance the falling off in the ionization of the more easily detached electrons. Again, some of the electrons ejected by the primary electrons may have enough energy to ionize on their own account; the total ionization may thus be increased by ionization due to the secondary electrons, and also by radiation excited by the impact of the primary electrons against the molecules of the gas.

When, as in the case of cathode rays in highly exhausted tubes or in that of the $\beta$ rays from radioactive substances, T is very large compared with Q, the number of ions produced per unit path is $n\pi e^4/QT$, and so varies inversely as the energy of the moving electrons. The experiments of Glasson on ionization by cathode rays, and of Durack on that by $\beta$ particles, seem to be in accordance with this result. If we measure the number of ions produced per centimetre in a gas at known pressure, for which we know the value of Q, we could determine $n$, the number of electrons in unit volume; as the pressure gives us the number of molecules, we could deduce in this way the number of electrons in each molecule.

*Ionization by Moving Ions.*—When the moving systems are ions instead of electrons, the collision between them and the electrons are collisions between masses of very different magnitudes, and in consequence a very much smaller fraction of the energy of the moving body is transferred to the electron than when the colliding bodies have equal masses.

The amount of energy transferred to the electron when the moving body has a mass M is equal to:—

$$\frac{4M_1M_2}{(M_1+M_2)^2}\cdot\frac{T}{1+\frac{4d^2T^2}{e^2E^2}\left(\frac{M_2}{M_1+M_2}\right)^2}$$

when $M_2$ is the mass of the electron and E the charge on the moving body. When, as in the case of the collision between an ion and an electron, $M_2$ is very small compared with $M_1$, this becomes

$$\frac{4M_2}{M_1}\cdot\frac{T}{1+\frac{4d^2T^2}{e^2E^2}\frac{M_2^2}{M_1^2}}$$

Thus, if Q is the ionizing potential, the minimum value of T, which will communicate this energy to the electron, is $\frac{1}{4}\frac{M_1}{M_2}Q$.

For the smallest possible ion, an atom of hydrogen, $M_1/M_2=1{,}700$, so that the minimum energy that will enable an ion to ionize a gas by knocking out an electron from a molecule is equal to 425Q. Q for many gases is about 10 volts; thus a positive ion must have at least energy represented by 4,250 volts to ionize the gas. With more massive ions the energy required for ionization would be still greater.

An ion with a mass equal to that of a molecule of oxygen would not ionize unless its energy were greater than 136,000 volts. Thus if any ionization by ions takes place in discharge tubes it must be due to ions of the lighter elements hydrogen or helium.

If the ion came into collision with the ion of the atom instead of with one of its electrons, it could, since its mass is comparable with that of the ion, give up to this a large fraction of its energy, a very much larger fraction than it is able to give to an electron. Inasmuch as it requires less work to dissociate a molecule into neutral atoms than to dissociate it into positively and negatively electrified ions, the result of such a collision is more likely to be the production of neutral atoms than of electrified ions.

An ion is, however, a much more complex thing than the simple charge of electricity which has in the preceding considerations been taken to represent the forces it exerts; and it may be that some strongly electronegative ions have such a strong attraction for an electron that when they pass through the molecule of a more electropositive element they are able to capture one of its electrons and carry it away with them. This type of ionization would differ from the ordinary type, inasmuch as in it the electron is never free; it produces negative ions, the other negative electrons.

It is evident from the preceding considerations that except in very intense fields it must be the electrons and not the ions which produce ionization by collision. Let us consider what are the chances of an electron acquiring sufficient energy in a uniform electric field; if the electron moved freely under the electric force X for a distance $l$ it would acquire $Xel$ units of energy. The electron in its course through the gas will come into collision with other bodies; its path will be deflected, possibly reversed, and in moving against the electric field it may lose all the energy it had previously acquired. Thus a collision of this type will destroy any ionizing power given to the electron by the electric force before the collision.

Let $\lambda$ be the average distance passed over by an electron between two collisions; then the chance of an electron moving through a distance $l$ without a collision is $e^{-\frac{l}{\lambda}}$; but if it moves through a distance $l$ it will acquire energy $=T=Xel$, hence the chance of an electron acquiring energy equal or greater than T is $e^{-\frac{T}{X\lambda}}$, and the chance that it should acquire energy between T and $T+dT$ is $\frac{d}{dT}\left(e^{-\frac{T}{X\lambda}}\right)dT$. If it possess this amount of energy the chance that it makes one ion per centimetre of path is $n\pi\frac{e^4}{T^2}(T/Q-1)$; hence the chance that an electron should make one pair of ions per centimetre of path is:—

$$n\pi e^4\int_0^\infty \frac{d}{dT}\left(e^{-\frac{T}{X\lambda}}\right)(T/Q-1)\frac{dT}{T^2}.$$

This may be written—:

$$n\pi e^4 \epsilon^{-\frac{Q}{X\epsilon\lambda}} 1/Q\, F\left(\frac{X\epsilon\lambda}{Q}\right),$$

where $F\left(\frac{X\epsilon\lambda}{Q}\right) = \int_0^\infty \frac{\epsilon^{-x \cdot \frac{X\epsilon\lambda}{Q}}}{\left(x \cdot \frac{X\epsilon\lambda}{Q}+1\right)^4} dx.$

Thus if $\alpha$ is the chance that an electron may produce one electron per unit path, since $\lambda$ for the same gas is inversely proportioned to the pressure $p$, $\alpha$ will be of the form $nf\left(\frac{X}{p}\right)$: and since $n$ is proportional to the number of molecules per unit volume, $\alpha$ may be written as $pf\left(\frac{X}{p}\right)$. When the spheres described round the electrons with radius $d$ do not overlap, $n$ will also be proportional to the number of electrons in the molecule. The greatest value of $d$ is $e^2/2Q$; hence if D, the distance between two electrons, is greater than $e^2/2Q$, there can be no overlapping; if D is less than this quantity there may be overlapping; since the value of $d$ diminishes as the kinetic energy of the electron increases, $n$ for very fast electrons will be proportional to the number of electrons in the molecule.

Some of the electrons will by adhesion to a neutral molecule become negative ions. Let the chance of an electron doing so while passing over 1 centimetre be $\gamma p$. If N be the number of electrons per c.c. at a place fixed by the coördinate $x$, then $\frac{dN}{dt}+\frac{d}{dx}(NU)$ = rate of increase of number of ions per c.c., where U is the velocity of the electron parallel to $x$.

The number of electrons passing through the unit of area in unit time is NU. The new electrons produced by the passage of them through the unit volume is $NU\alpha$, while $NU\gamma p$ will disappear; hence:—

$$\frac{dN}{dt}+\frac{d}{dx}(NU) = NU(\alpha-\gamma p)+q \quad . \quad . \quad . \quad (19),$$

where $q$ is the ionization due to external sources; when things are in a steady state $dN/dt=0$, and the solution of the equation, when the electric field may be taken as constant from one electrode to another, is:—

$$NU = Ce^{(\alpha-\gamma p)x} - \frac{q}{\alpha-\gamma p}.$$

Most of the experiments on this subject have been made without external ionization; a supply of electrons has been obtained from the cathode, either by raising it to incandescence or by exposing it to ultra-violet light. In such cases $q=0$, and

$$NU = \iota_0 e^{(\alpha-\gamma p)x} \quad . \quad . \quad . \quad (20),$$

where $\iota_0$ is the number of electrons emitted in unit time from the cathode. Townsend, and Townsend and Kirkby have determined the value of $\alpha-\gamma p$ for various gases and over a considerable range of pressure. A series of these values for air are given in the following table:—

| X = volts per cm. | Pressure (mm.) | | | | |
|---|---|---|---|---|---|
| | ·17 | ·38 | 1·10 | 2·1 | 4·1 |
| 20 | ·24 | .. | .. | .. | .. |
| 40 | ·65 | ·34 | .. | .. | .. |
| 80 | 1·35 | 1·3 | ·45 | ·13 | .. |
| 120 | 1·8 | 2·0 | 1·1 | ·42 | ·13 |
| 160 | 2·1 | 2·8 | 2·0 | ·9 | ·28 |
| 200 | .. | 3·4 | 2·8 | 1·6 | ·5 |
| 240 | 2·45 | 3·6 | 4·0 | 2·35 | ·99 |
| 320 | 2·7 | 4·5 | 5·5 | 4·0 | 2·1 |
| 400 | .. | 5·0 | 6·8 | 6·0 | 3·6 |
| 480 | 3·15 | 5·4 | 8·0 | 7·8 | 5·3 |
| 560 | .. | 5·8 | 9·3 | 9·4 | 7·1 |
| 640 | 3·25 | 6·2 | 10·6 | 10·8 | 8·9 |

It will be seen that, when X is given, the increase in the number of electrons reaches a maximum for a particular pressure. From general reasoning this must be so, for if $p=0$ there will be no collisions to make fresh electrons, and if $p$ is infinite the free path of the electrons will be so small that they cannot acquire sufficient energy to ionize the gas. Since $\alpha$ is of the form $pf\left(\frac{X}{p}\right)$, and $\gamma$ does not depend upon $p$, $\alpha-\gamma p$ will be a maximum when

$$f'\left(\frac{X}{p}\right) - \gamma - pf'\left(\frac{X}{p}\right)\cdot\frac{X}{p^2}=0,$$

or when $f\left(\frac{X}{p}\right) - \gamma = f'\left(\frac{X}{p}\right)\frac{X}{p}$. This equation determines $X/p$; hence the critical pressure will be proportional to the electric force.

At this critical pressure $X\epsilon\lambda$ bears to Q a ratio which depends upon the way in which the chance of an electron ionizing by a collision depends upon the energy of the electron. If, for example, the chance were independent of this energy, provided the energy were greater than Q, the maximum current would be when $X\epsilon\lambda=Q$; this relation would not hold for other and more probable laws connecting ionizing power with the energy, but we should expect that for any such law the ratio of $X\epsilon\lambda$ to Q would neither be very large nor very small.

Since the electrons cannot begin to ionise until their energy is equal to Q, and to attain this energy they must pass through a distance Q/Xe, it is clear that we ought in such an equation as (19) to write $x-Q/Xe$ in place of $x$. If V is the potential difference between the plates, $X=V/d$, so that $x-Q/X\epsilon = x-dQ/V$ if Q is measured in volts. Thus in finding the current between two electrodes we must, if we use equation (19), write $d\left(1-\frac{Q}{V}\right)$ instead of $d$.

Partz (*Verh. d. Deutsch. Phys. Gesell.* xiv, p. 60) has shown that theory and experiment agree better by this change.

*Spark Discharge.*—The production of ions by moving electrons will not by itself explain why a current of electricity can be maintained through a gas by an electric field when all other sources of ionization are excluded. The electrons are continually being driven towards the anode, and unless there is some source of supply near the cathode the ionization and therefore the current will rapidly come to an end. One way in which the electrons could be supplied by the action of the electric field would be by the positive ions which strike against the cathode communicating so much energy to the anode that it [illegible] e. Since [illegible] ns these [illegible] e, which will ionize the gas and produce fresh [illegible] to strike against the cathode and keep it hot. [illegible] ns in the arc discharge when the cathode is very [illegible] n-descence by the discharge. [illegible] of energy put into the arc. There are, however, other forms of continuous discharge where the cathode does not become incandescent, so that there must be other ways in which the supply of electrons is maintained. From what we know about ions there are several ways in which this might occur.

It has been found by experiment—(Füchtbauer, *Ann. der Phys.* 23, p. 301 (1907); Saxen, *Ann. der Phys.* 38, p. 319 (1912); Baerwald, *Ann. der Phys.* 41, p. 643 (1913); 42, p. 1207 (1913)—that electrons are emitted from metals when these are bombarded by high-speed positive ions even though the metal is not raised to incandescence. According to Baerwald the emissions of electrons from metals bombarded by positive hydrogen atoms does not become appreciable until these have an amount of energy exceeding that represented by 900 volts. We know too that, when the electric discharge passes through a gas, radiation capable of ionizing a gas through which it passes, or of ejecting electrons from a metal on which it falls, is an accompaniment of the discharge. Again positive ions ionize a gas through which they pass. This was shown by McClelland, who found that the relation between the potential difference and the current from a hot wire anode surrounded by gas at low pressure was represented by a curve like that shown in

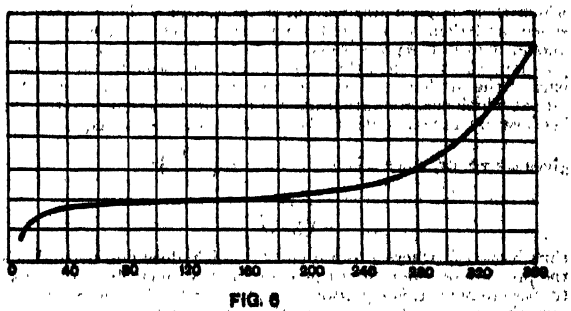

FIG. 6

fig. 6. The hot wire furnishes positive ions as well as negative ones, and the curve shows that fresh ions are formed when the potential difference is greater than about 200 volts. This is a much greater potential difference than that needed to produce ionization by electrons, but it is smaller than would be expected by the considerations given above. As it requires less work to eject an electron from a metal than from a molecule, we should expect that if 200 volts ions could eject electrons from a gas through which they pass they would be able to do so from a metal against which they strike, but from Baerwald's experiments much more energy than 200 volts

is required for this purpose. In McClelland's experiments the ionization might have been into positive and negative ions rather than into positive ions and electrons; before the negative ions could be efficient for ionization by collision they would have to undergo further dissociation into electrons and uncharged molecules. Curves similar to that in fig. 6 have also been obtained by O. W. Richardson. Pawlow (*Proc. Roy. Soc.* A. 90, p. 398) and also Franck and E. v. Bahr (*Verh. d. Deutsch. Phys. Ges.* xvi, p. 57, 1914) came to the conclusion from their experiments, that ionization was produced by positive ions even when their energy did not exceed a few volts; indeed they could not get any evidence of a minimum to the ionizing voltage. Horton and Davies (*Proc. Roy. Soc.* 95, p. 333) could not detect any ionization in a gas by positive helium ions when the energy was due to 200 volts. They ascribe the ionization observed by Pawlow and Bahr and Franck to photo-electric effects; they consider, however, that positive helium ions can liberate electrons from a metal against which they strike if their energy exceeds 20 volts. Baerwald considers that it requires an energy measured by 900 volts before positive ions can liberate electrons from metals.

There are thus at least four methods by which the supply of electrons near the cathode necessary to maintain the discharge can be obtained. The gas near the cathode may be ionized by positive ions or by radiation, or the cathode itself may emit electrons under the impact of positive ions or by the incidence of radiation.

When the gas is at a low pressure the appearance of the discharge has well-marked characteristics which may throw light on the method by which the electrons are produced and the place from which they start. The discharge near the cathode is represented in fig. 7; near the cathode we have a velvety glow, then a space comparatively dark called the cathode dark space; this joins on to

a brightly luminous region called the negative glow; passing through this region, and making themselves evident by the luminosity they excite when they strike against the glass wall of the vessel in which the gas is contained, are the cathode rays. These have been shown to be electrons moving with high velocity. These electrons have been liberated by the action of the electric field and have acquired their velocity under the action of that field. The velocity of the cathode rays has been measured, and it has been found that practically all of them have the same velocity. This shows that they must have all fallen through the same potential. They would do this if they all started from the cathode itself, but if they had originated by the ionization of the gas in the dark space in front of the cathode, some would have started from one place and some from another, and they would have acquired different velocities. This is strong evidence in favour of the cathode itself being the primary source of the electrons which maintain the discharge. When a supply of electrons is produced by processes taking place at the cathode, ionization by collisions of electrons with the molecules of the gas is sufficient to maintain the discharge through the interval between the negative glow and the anode. This interval, as will be seen from fig. 7, is made up of a short part next the negative glow in which there is comparatively little light, called the Faraday dark space, and then a long uniform portion reaching right up to the anode. Unless the pressure is very low or the spark very short this position, which is called the positive column, forms by far the larger part of the discharge. The discharge here will be maintained if the rate at which electrons are produced by collision is equal to the number lost by recombination. When this is the case, equation (19) gives $\alpha=\gamma p$, or, since $\alpha$ is of the form $pf\left(\frac{Q}{X\rho\lambda}\right)$,

$$f\left(\frac{Q}{X\rho\lambda}\right)=\gamma,$$

thus $X\rho\lambda=cQ$, where $c$ is a quantity which does not depend upon the pressure or strength of the field; as $\lambda$ is inversely proportioned to the pressure, this equation is equivalent to $X=c_1p$, when $c_1$ is a quantity which will depend on the nature of the gas and possibly on the intensity of the current. If $l$ is the length of the positive column the difference in potential between the anode and the end of the positive column next the cathode is $lX$, *i.e.* $lc_1p$.

Between the cathode itself and the negative glow there is a fall of potential, called the cathode potential fall, which, when the current carried by the discharge is not large, is independent of the current and the pressure of the gas; it depends upon the nature of the gas and the material of which the electrodes are made. If $V_0$ is the cathode fall, then (neglecting the change in potential in the negative glow and the Faraday dark space, which has been found by experiments to be very small) V, the potential difference between the anode and cathode will be given by the equation

$$V=V_0+c_1lp \quad . \quad . \quad . \quad (21).$$

It is assumed that the length of the spark is greater than that of the dark space D: at pressures comparable with that of the atmosphere, D is a very small fraction of a millimetre, but at the low pressures which can easily be obtained in highly exhausted vessels D may be several centimetres. It is to be noticed that V is a linear function of $lp$, and $lp$ is proportional to the mass of gas between the electrodes; hence as long as the mass of gas between the electrodes remains unaltered the potential difference required to maintain the spark will be constant. This law, which was discovered by Paschen in 1889 as the result of a long series of experiments, is known as "Paschen's law." It has been found to be in agreement with the very numerous investigations which have been made on the potential difference required to produce a discharge in an approximately uniform electric field such as that which exists between two slightly curved electrodes.

The relation (21) does not give any indication of the relation between the potential difference and the spark length when the latter is exceedingly small. When the spark length falls below a critical value which is inversely proportional to the pressure, and which in air at atmospheric pressure is about ·01 mm., the spark potential increases rapidly as the spark length diminishes; this was first observed by Peace. A simple way of demonstrating it is to use slightly curved electrodes and to observe the path of the spark as these are brought closer together. Until the electrodes get very close together the spark passes along the shortest line between them, but as they approach each other a stage is reached where the spark no longer passes along the shortest line but goes to one side, taking a longer path, showing that it is easier to produce a long spark than a short one. The relation between the potential difference and the spark length for several gases has been determined by Carr, who finds that Paschen's law that the potential difference depends only on $pd$ is also true for very short sparks; Paschen's own experiments were made with sparks considerably longer than the critical value. Fig. 8 represents Carr's results for

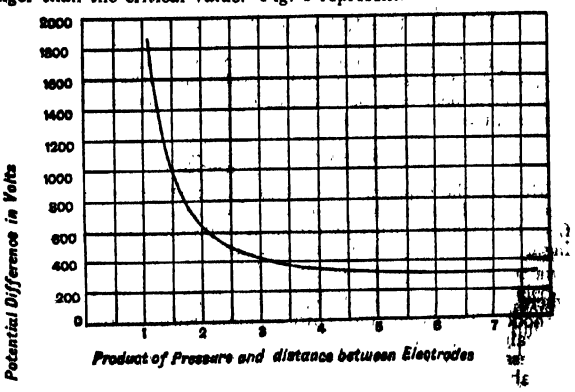

FIG. 8

the relation between V and $pl$. The results of Carr and Strutt's experiment for the minimum spark potential, and the value of $pl$, at which it occurs, are given in the following table:—

| Gas. | Minimum Spark Potential in volts. | $pl$. |
|---|---|---|
| Air | 341 S | 5·7 |
| Nitrogen | 251 S | 6·7 |
| Oxygen | 455 C | |
| Hydrogen | 302–308 S<br>278 C | 14·4<br>.. |
| Carbonic acid | 419 C | 5·1 |
| Sulphur dioxide | 457 C | 3·3 |
| Nitrous oxide | 418 C | 5 |
| Sulphuretted hydrogen | 414 C | 6 |
| Acetylene | 468 C | .. |
| Helium | 261 S | 35 |

The curves are very flat in the neighbourhood of the minima, so that the critical values of $pl$ may be subject to considerable errors. Strutt found that even very small traces of impurity produced very large increases in the values of the minimum spark potential in nitrogen and helium; these are gases where, as we have seen, such traces produce large diminutions in the mobility of the negative ion. The existence of a minimum for the spark potential and a critical spark length follow from the view that the spark is maintained by the emission of electrons from the cathode owing to its bombardment by positive ions. For if $\omega$ be the number of cathode rays emitted from unit area of the cathode per second, at a distance $x$ from the cathode $\omega e^{-\alpha x}$ electrons will stream through unit area per second and will produce

per second $\alpha n e^{-\alpha x}$ positive ions per c.c. These positive ions will proceed up to the cathode, and a certain percentage will react and bombard it. Let the chance of the ion reaching the cathode with undiminished energy be $e^{-\beta x}$; then the energy with which it strikes the cathode is $Ve$, when V is the potential at $x$, so that the energy in the ions striking unit area of the cathode per second is $\int_{0,a} \frac{l}{\alpha} \alpha n e^{-\alpha x} e^{-\beta x} V e dx$. The rate of emission $\iota$ will be proportional to this energy, so that,

$$\iota = K\omega \int_{0,a}^{l} \alpha e^{-(\beta-\alpha)x} V e dx \quad . \quad . \quad . \quad (22).$$

when $K$ is a quantity that may depend on the material of which the cathode is made and on the kind of positive ions which strike against it, but will not depend on the pressure of the gas. If W be the potential difference between the anode and cathode, and $l$ the distance by which they are separated, V may be written in the form $Wf(x/e)$, where $f(0)=0$ and $f(1)=1$. Putting $x/l=y$, equation (7) gives

$$1 = KWale \int_0^1 e^{-(\beta-\alpha)ly} f(y) dy \quad . \quad . \quad . \quad (23).$$

Now both $\alpha$ and $\beta$ are proportional to the pressure $p$ of the gas, so that $l$ and $p$ only occur in the combination $lp$; thus in the most general case W the spark potential will be a function of $lp$; this is Paschen's law, which has been shown by Carr to hold, down to very low pressures and spark lengths. When $lp$ is very small (23) reduces to

$$W = \frac{1}{Kale} \frac{1}{\int_0^1 f(y) dy}.$$

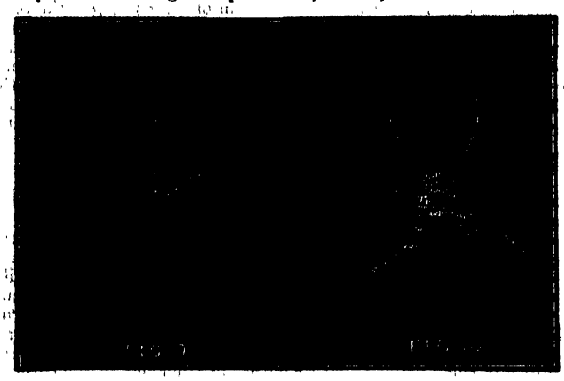
Thus the potential required to produce very short sparks varies inversely as the length of the spark, so that to produce an infinitely small spark would require an infinitely large potential. The rapid increase in the spark potential as the spark length diminishes is shown by the curve in fig. 8. The spark potential will also be infinite when $l$ is infinite so for some intermediate spark length the potential must be a minimum. We see from the form of equation (23) that if $W_0$ is the minimum potential, $KW_0\alpha/(\beta-\alpha)$ is a constant, depending only on the form of the function $f$, and also that, if L is the spark length when the potential is a minimum, $L(\beta-\alpha)$ is another constant depending also on the form of the function; if $f(y)=y$ we get $L=\frac{1\cdot8}{\beta-\alpha}$, thus the critical spark length will depend upon the gas, but not upon the material of which the cathode is made: the minimum potential $W_0$ is equal in this case to $(\beta-\alpha)2\cdot2/Ke\alpha$ or $W_0=\frac{1\cdot2}{L\cdot Ke\alpha}$. Now $1/Ke$ is the potential difference, $u$, through which a positive ion must fall to get enough energy to liberate one electron from the cathode, and $aL$ is the number of electrons produced when an electron passes over the critical spark length. If this number is $n$, $W_0=\frac{1\cdot2u}{n}$. We may summarize the argument as follows: if $p_1$ is the chance of a positive ion liberating an electron from the cathode, $p_2$, the chance of that electron making an ion in the space $d$, then the probability that the original positive ion will be replaced by a new one is $p_1p_2$, and if the process is to be regenerative $p_1p_2$ must be unity.

Since $K$ may depend on the metal against which the ion strikes as well as upon the ion itself, the minimum potential might depend upon the material of which the cathode is made. Baerwald found, however, that for many of the ordinary metals there was not much difference in the numbers of electrons they emitted when bombarded by positive ions, so that with all such metals for cathodes the critical spark should be the same. There is very considerable evidence that the minimum potential required to produce a spark is equal to the cathode fall of potential when the length of discharge is much greater than the critical spark length, and Mey has shown that the cathode fall of potential is appreciably less when the cathode is made of Al, Mg, Na or K, than when it is made of Pt, Hg, Cu or Ag.

The mechanism we have hitherto considered involves the ionization of the gas between the electrodes, and no spark could pass across a [illegible] other method by which a discharge [illegible] was a stray [illegible] then under the action of [illegible] would be [illegible] at the anode; by the impact [illegible] ation would be [illegible] ated, which would fall on the [illegible] if it were [illegible] gh to liberate [illegible] the original [illegible] would be re[illegible]hode to th[illegible] it is prob[illegible] perfect insulator for the very intense fields.

The linear relation $V=V_0+\alpha/p$ has been obtained on the assumption that the direction of the electric force was the same in all parts of the field; this is only true when the dimensions of the electrodes are large compared with the distance between them. The potential difference required to produce a spark of a particular length depends upon the size of the electrodes between which the spark passes, and is not a linear function of $lp$, where $p$ is the pres[illegible] the lin[illegible] ark po[illegible] ay be[illegible] the spa[illegible] for ele[illegible] 5 [illegible] ter of [illegible] 5 [illegible]

In this connexion [illegible] is sufficiently intense at [illegible] of ions; these may red[illegible] les, and by their electrost[illegible] bu-tion of the electric fore[illegible] the spark than that prior to th[illegible] ate this [illegible] illel plates [illegible] m-selves so that [illegible] m. Thus [illegible] re-gate [illegible] the distance of the "critical spark length" or thickness of the cathode dark space a difference of potential equal to the minimum spark potential. This would ensure that from close to the cathode there was a continual emission of electrons, and even though the electric field from this place to the anode was too feeble to give an electron enough energy to ionize the gas, the electrons coming from the cathode would be able to carry a small current, though this part of the discharge might not be luminous. The ions here would be all of one sign, so that the electric force will increase up to the anode. If the current is gradually increased, the place where the electric force will just rise to the value necessary to make the electrons ionize will be close to the anode. When this occurs a supply of positive ions will start from the anode and move towards the cathode, accompanied by luminosity close to the anode and very faint luminosity through the rest of the tube. The introduction of the positive ions into the region between the anode and cathode will diminish the retarding effect of the negative space charge which existed in this region, so that the current will increase. This increase in current will again increase the ionization at the anode, and thus the supply of positive ions. In this way there might be a supply of electrons coming from the cathode, and of positive ions from close to the anode, which will maintain the current in spite of the fact that between these places there was a region where the electric force was below that required to produce ionization by collision, and the potential difference between the electrodes less than that calculated on the supposition that the electric force was uniform from one to the other. We should expect from these considerations that, if the electric force at any point were intense enough to produce ionization by collision, some discharge would take place.



Russell (*Phil. Mag.* 6. xi., p. 237) states that the results of the different experiments made on the potential difference required to produce sparks of various lengths between spherical electrodes of various radii are in good agreement with the rule that the discharge takes place in air at atmospheric pressure if the electric force at any point in the field before discharge begins is as great as 37,000 volts per centimetre. This value agrees well with that required to make electrons produce in air at atmospheric pressure other ions by collisions.

The curious lag observed by Warburg between the application of the potential difference and the passage of the spark, which may amount in extreme cases to several seconds, *e.g.* when the applied potential is only a very little greater than that required to produce the spark, is naturally explained as the time necessary for the ions to distribute themselves so as to produce the distribution of potential required for the discharge.

The discharge of electricity from points affords a good illustration of the preceding considerations. Suppose that the electrodes are a needle point and a plane. When the discharge first begins the only place where any light is to be seen is close to the point; the current between the electrodes is very small; as the potential difference increases a stage is reached where light begins to appear close to the points, the space between the point and plate being quite dark. This stage is marked by a large increase in the current. With further increase in current the luminosity extends into the gas and ultimately stretches from one electrode to another.

The potential required to start the discharge is less where the point is negative than where it is positive. This is what might be expected, for to maintain the discharge from the negative point there must be (1) ionization of the gas by the outgoing electrons, and (2) liberation of electrons by the incoming positive ions, while when the point is positive there must be (1) ionization of the gas by outgoing positive ions, and (2) liberation of positive ions by the impact of incoming electrons; as the process is not the same as for the negative point we should expect that there would be a difference between the potentials. It is not only the potential difference which is affected but the type of discharge. This can be shown by allowing the point discharge to pass in the neighbourhood of a photographic plate. Beautiful figures are found on developing the

plate, and the character of these is different according as the point is positive or negative. Figures 9 and 10 represent discharges from positive and negative points respectively.

The discharge from a negative point is in some gases very much influenced by the purity of the gas; thus Warburg found that the discharge from a negative point in nitrogen increased about fifty times by removing the last trace of oxygen from the nitrogen, though this had little or no effect upon the discharge from a positive point. This can be accounted for by the discovery of Franck and Hertz that in very pure nitrogen the electron does not become a negative ion and has a very high mobility. This is true for the inert gases as well as for nitrogen, and Pryzibram has shown that the difference between the discharges from positive and negative points is exceptionally large in these gases.

*Electrical Wind.*—The electrified ions starting from the point in a point discharge sets the gas in the neighbourhood of the point in motion producing a current of air, called the "electrical wind." The momentum gained by the air is lost by the point, so that there is a backward force acting on the point, which has often been measured. This force, as well as the electrical wind, is smaller when the point is negative than when it is positive; this difference is especially marked at pressures low enough to make the negative ion have an abnormally large mobility.

*Relation between Potential Difference and Current.*—The potential difference required to maintain a discharge will depend upon the current passing in the discharge. The relation between the current and potential difference for discharge through gases is often a very complicated one. We should expect that this would be so, for in the spark discharge, for example, the potential difference is made up of the cathode fall of potential (this increases with the current) and a uniform force along the rest of the discharge, and this force in many cases diminishes as the current increases. Thus whether increases of current produce an increase or decrease in the potential difference will depend on the relative contributions of these two parts.

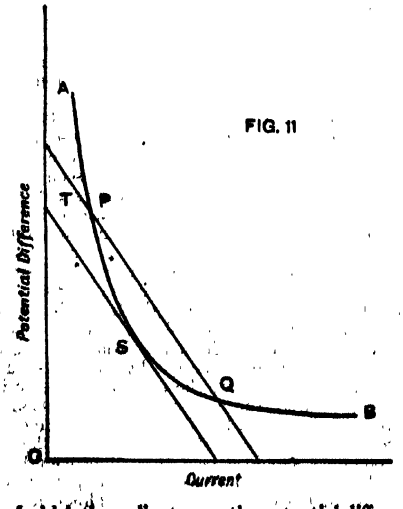


FIG. 11

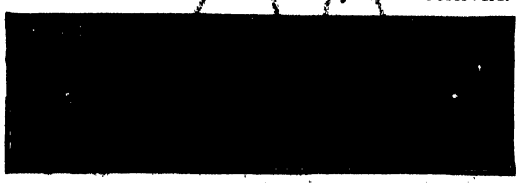
A curve of which the ordinates are the potential difference between the electrodes and the abscissæ the current through the gas is called the "characteristic curve" for the discharge. Suppose that the current sent through a gas by a battery of cells of electromotive force $E_0$ is required. If R is the resistance of the curves connecting the battery with the electrodes in the gas, then $E_0 - Ri$ is the potential difference between the electrodes in the gas, and one relation between this potential V and the current is represented by the straight line $V = E_0 - Ri$. The other relation is that represented by the characteristic curve; the values of the current through the gas and the potential difference between the electrodes will be determined by the points of intersection of this straight line and the characteristic curve. Unless the straight line cuts the curve there can be no discharge through the gas; on the other hand, the straight line may cut the characteristic curve in more than one point, indicating that there is more than one type of discharge. Some of these types may, however, be unstable and thus impossible to realize. Thus, for example, if the current is increased by $\delta i$ the difference of potential given by the battery between the electrodes is diminished by $R\delta i$; if V is the potential difference between the electrodes required to send a current $i$ through the gas, then, when the current is increased by $\delta i$, the increase in the potential required is $\frac{dV}{di}\delta i$; thus unless $\frac{dV}{di}\delta i$ is less than $-R\delta i$, or $-\left(\frac{dV}{di}+R\right)\delta i$ be positive, the diminished potential supplied by the battery will not be sufficient to maintain the increase in the current, this increase will stop, the current will return to its original value, and the discharge will be stable; thus if $R+\frac{dV}{di}$ is positive the discharge will be stable. If, however, $R+\frac{dV}{di}$ is negative the fall in potential required to maintain the increased current is so great that, in spite of the diminution of the potential difference supplied by the battery, the residue is great enough to maintain the increased current, the increase in the current will continue, and the discharge will be unstable. Thus the condition for stability is that $R+\frac{dV}{di}$ should be positive, a result first given by Kaufman. This result is equivalent to the condition that for stability the straight line must, at the point where it cuts the characteristic curve, fall more steeply than the tangent to the curve at that point. Thus if APQB is the characteristic curve, and if the straight line cuts it at PQ, the type of discharge represented by P is unstable, and that by Q stable. Keeping the electromotive force of the battery constant and increasing the resistance will make the straight line steeper, and Q will move to the left and the current through the tube will decrease; when the line gets so steep that it touches the curve at S, the minimum value of the current consistent with the maintenance of this type of discharge by the electromotive force supplied by the battery will be reached, and any further diminution of the current will result in the extinction of this type of discharge. It is a well-known fact that the existence of most types of luminous discharges requires the current to be above a certain critical value which depends upon the external force. The electric arc is perhaps the most familiar example of this; as the characteristic curve for the arc discharge is a rectangular hyperbola represented by the equation $V = a + \frac{b}{i}$. We can easily show that if the external electric force is E, the maximum resistance which can be introduced into the circuit without extinguishing the arc is $(E-a)^2/4b$, and the smallest current compatible with the existence of the arc $2b/(E-a)$. For any stable type of discharge we see that an increase in the external electromotive force will result in an increase of current; at a point corresponding to an unstable condition it produces a diminution.

*Structure of the Discharge.*—The structure of the discharge at atmospheric pressure is on so fine a scale that its details can only be made out with difficulty; as the pressure is reduced the scale gets larger and larger, until, when the pressure is reduced to that due to a millimetre or so of mercury, the details of the structure become very conspicuous. The appearance of the discharge at



such a pressure is shown in fig. 12, and we see that it is built up of several constituents of very different types. We have already

when considering the spark discharge given a general description of some of them; there are, however, some features which require further discussion.

Starting from the cathode we find a thin layer of luminous gas, the colour of which depends on the kind of gas through which the discharge is passing. In most gases the light appears to reach right up to the cathode, but in helium Aston has shown it is separated from it by an exceedingly thin dark space. This luminous layer is sometimes called "Goldstein's first layer"; next to this we have a region where there is comparatively little luminosity called "Crookes' dark space," the boundary of this space being approximately the surface traced out by normals to the surface of the cathode of constant length. The thickness of the dark space, which is of the order of the critical spark length, depends upon the pressure of the gas, varying approximately as the reciprocal of the pressure for air; at the pressure of 1 mm. of mercury the thickness of the dark space is about 2 mm., so that at atmospheric pressure the thickness would not be much more than about 1/400 of a millimetre. If the pressure remains constant and the current through the tube is increased, the thickness of the dark space remains unaltered until the current is large enough to cover the whole of the cathode with the luminous glow; after this stage is reached any further increase in the current causes a diminution in the thickness of the dark space. Starting from the boundary of the dark space there is a brightly luminous region called "the negative glow." The function of the parts of the discharge from the cathode to the negative glow is to produce the supply of electrons from the neighbourhood of the cathode necessary to keep the discharge going. The dimensions of this part of the discharge are independent of the distance between the cathode and anode; at very low pressures this part may occupy a length of several centimetres, but at atmospheric pressure they are crowded into a very small fraction of a millimetre and as far as length goes occupy a negligible portion of the sparks at such pressures. The Crookes' dark space, though it appears dark in contrast to the negative glow, is not devoid of luminosity; indeed Seeliger, who has made a spectroscopic examination of the dark space, finds that there are some lines, such as the Balmer series lines, which are almost as bright in the dark space as in the negative glow. But many lines are much stronger in the negative glow than in the dark space.

Beyond the negative glow there is another comparatively dark region called the "Faraday dark space"; the length of this is very variable even when the pressure is constant, as it is sensitive to any change in current. Beyond this and reaching right up to the anode is a luminous column, called the positive column. The luminosity in some cases is fairly uniform in intensity, but when the pressure and current are between certain limits this column may exhibit remarkable alternations of dark and bright spaces called striations, such as are shown in fig. 18. Under some circumstances a dark space round the anode has been detected by several observers.

When the distance between the electrodes is considerable and the pressure not very low, the positive column forms by far the greater part of the discharge; thus at atmospheric pressures all but a fraction of a millimetre of the discharge next the cathode will consist of the positive column.

*Distribution of the Electric Force along the Discharge.*—The electric force is very large indeed in the part of the dark space next the cathode, but diminishes rapidly towards the negative glow. In the negative glow itself it is smaller than in any other part of the discharge; passing the negative glow, the electric force increases in the Faraday dark space, until the positive column is reached. When the positive column is of uniform luminosity the electric force in the column is constant until quite close to the anode, when there is an abrupt change of potential of about 20 volts, called the anode fall of potential. When the positive column is striated, the alternations of luminosity in the positive column are accompanied by alternations in the intensity of the electric force, the maxima of the electric force occurring at the bright parts of the stria, the minima at the dark. From the equation $\frac{dX}{dx} = 4\pi\rho$, where X is the electric force in the direction of x and $\rho$ the density of the electrification, we see that there is an excess of positive electricity in the cathode dark space and of negative in the Faraday dark space; in a uniform positive column there is no appreciable excess of electricity of one sign over that of the opposite, while in the striated positive column there is an excess of negative electricity on the cathode side of a bright part of a striation and of positive on the anode side.

*Cathode Fall of Potential.*—Until the glow next the cathode covers the whole of the electrode the difference of potential between the cathode and the negative glow is constant, depending on the gas and the material of which the cathode is made, but being independent of the pressure of the gas and the strength of the current. This constant difference of potential is called the "cathode fall of potential," and there is evidence to show that it is equal to the minimum potential that can produce a spark through the gas. Its value, as determined by Mey for different gases and different electrodes, is given in the following table, which includes also Matthies' results for $Cl_2$, $Br_2$, $I_2$:—

| Gas | Pt | Hg | Ag | Cu | Sc | In | Al | Mg | Na | Na-K | K |
|---|---|---|---|---|---|---|---|---|---|---|---|
| $O_2$ | 369 | .. | .. | .. | .. | .. | .. | .. | .. | .. | .. |
| $H_2$ | 300 | .. | 295 | 280 | 230 | 213 | 190 | 168 | 185 | 169 | 179 |
| $N_2$ | 232 | 226 | .. | .. | .. | .. | .. | 207 | 178 | 125 | 170 |
| He | 226 | .. | .. | .. | .. | .. | .. | .. | 80 | 78·5 | 69 |
| Arg | 167 | .. | .. | .. | .. | .. | 100 | .. | .. | .. | .. |
| Cl | 295 | .. | .. | .. | .. | .. | .. | .. | .. | .. | .. |
| Br | 355 | .. | .. | .. | .. | .. | .. | .. | .. | .. | .. |
| I | 377 | .. | .. | .. | .. | .. | .. | .. | .. | .. | .. |

When the current is so large that the luminous glow completely covers the cathode, the potential difference between the cathode and the negative glow increases as the current increases, while the thickness of the dark space diminishes. Mr. Aston, as the result of experiments made with very large parallel plate electrodes, found the following relations between V the cathode fall of potential, $i$ the intensity of the current, D the thickness of the dark space, and $p$ the pressure of the gas—

$$D = \frac{A}{p} + \frac{B}{\sqrt{i}}$$

$$V = E + \frac{F\sqrt{i}}{p}$$

These relations are empirical, and must not be taken to imply that the dark space would increase indefinitely if the current were diminished without limit. Aston also found that the thickness of the dark space as well as the cathode fall of potential depended upon the material of which the cathode is made. If the space round the cathode is restricted so that the dark space has not room to develop (for example, if the cathode is placed in a narrow tube), then, as soon as the dark space reaches the walls of the tube, the cathode fall begins to increase, and increases very rapidly as the pressure diminishes and the thickness of the free dark space exceeds more and more the space available round the cathode. This is due to the same cause as that which makes the spark potential increase rapidly when the spark length falls below the critical value. This result is utilized to make "electric valves," *i.e.* tubes through which a current will only pass in one direction. For if electrodes are put in a tube which is narrow at one end and very wide at the other, the development of the negative glow will be restricted when the cathode is at the narrow, but not when it is at the wide end of the tube: a discharge through the bulb will pass much more easily when the wide end is cathode than when it is anode, so that even if the electrodes are made alternately positive and negative the discharge through the tube will only be in one direction.

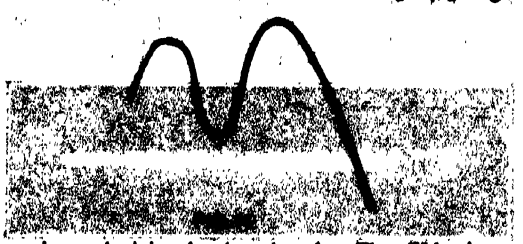
A very important question in connexion with the cathode fall of potential is whether the fall is continuous throughout the dark space or whether an appreciable fraction of it occurs abruptly at the surface of the cathode: Aston, who measured the distribution of potential near a very large flat cathode, came to the conclusion that there was no abrupt fall at the cathode. Westphal, on the other hand, found in his experiments an abrupt fall of potential quite close to the cathode amounting to 20% or more of the total cathode fall. The question is important in connexion with the mechanism of the discharge, for if the fall is so abrupt that it occurs within molecular distances the electric force at the surface of the cathode might be so great that the electrons would

be drawn out of the cathode without the necessity for the bombardment by positive ions. It is interesting in this connexion to notice that Skinner has shown that the anode "fall of potential" occurs quite abruptly, as far as can be tested by experiment; this, again, if the fall took place in molecular distances might be sufficient to drag positive ions out of the anode itself. By using a cathode heated to incandescence, and therefore emitting a plentiful supply of electrons, we can reduce the cathode fall of potential to a small fraction of its normal value; we cannot, however, with a luminous discharge get rid of the anode fall; thus in the arc discharge the anode fall of potential is greater than the cathode fall. Matthies has shown that, in chlorine, bromine and iodine, the anode fall of potential may rise to hundreds of volts, that in air or hydrogen being only about 18 volts. Reichenheim and Gehrke utilized this fact to get positive ions of sodium and potassium projected with great velocity. They made the anode of a mixture of the halogen salts of these metals and graphite, and worked at a very low pressure; under the action of the discharge the halogens were liberated from the anode, and the large anode fall they produced was sufficient to project sodium and potassium ions from the anode with great velocity; this stream of positive ions constitutes what is known as "anode rays."

The electric force in the positive column is a linear function of the pressure; it depends slightly on the diameter of the tube through which the discharge is passing; it also depends on the current through the tube; in most cases, though not invariably, an increase of current produces a decrease in the electric force. The condition determining the electric force in the positive column is that it should give to an electron during its free path the amount of energy that will enable the electrons to produce by collisions as many ions per second as are lost during the same time by recombination.

*Striated Discharge.*—The form of discharge when the positive column is striated is so beautiful and remarkable that it has attracted a great deal of attention. To get this type of discharge the current and pressure must be within certain limits. The striations are developed more readily in mixtures of gases than in a pure gas; in fact some physicists have advanced the view that they could not be obtained in an absolutely pure gas. There is no doubt, however, about their occurrence in gases in which great attention has been paid to purification. Nerbeck could not get them in pure nitrogen or pure helium, though they were conspicuous as soon as a trace of impurity was admitted. Nitrogen and helium are gases in which, when pure, the carrier of negative electricity is always an electron; in these gases the electron does not join on to a molecule and become a negative ion. Spottiswoode found that, in some cases when the positive column showed no signs of striation when observed in the usual way, striations moving rapidly down the tube could be seen when the discharge was observed after reflection in a rapidly rotating mirror. Aston and Kikuchi, who have studied this effect in neon and helium, are of opinion that the striations are moving in these gases with the velocity of sound; it must be remembered, however, that the velocity of sound in many gases is of the same order as the velocity of a positive ion under the electric forces in the positive column, so that this result does not necessarily prove that the moving striations are analogous to sound waves.

The distance between the striations increases as the pressure diminishes (in hydrogen the distance is inversely proportional to the square root of the pressure); it depends upon the size of the tube: the striations are nearer together in narrow tubes than they are in wide. The distance between the striations also depends upon the current. When several gases are in the tube, spectroscopic observation of the bright parts of the different striations shows that we may have one set of striations corresponding to one gas, another to another and so on. Thus Crookes observed in a tube containing hydrogen three sets of striations, one set red, another blue and a third grey; the spectroscope showed that the first was due to hydrogen, the second to mercury vapour and the third to hydrocarbons. The striations are often curved with their concavities turned to the anode.



To get a general idea of the causes which might give rise to stratification, let us consider a case where the current is carried entirely by electrons, the positive ions being regarded as immovable in comparison with the electrons. Let us imagine a stream of electrons coming from the negative glow; the electric force in this region is exceedingly small, so that these electrons will have very little energy and will be unable to ionize the gas; the electrification in this part of the tube will be that due to the electrons and thus will be negative, so that the electric force will increase as we approach the anode; as the electric force increases the energy of the electron increases, and the electron will acquire enough energy to enable it to ionize the gas and produce positive ions and electrons; the increase in the number of ions will check the rate of increase in the electric force. The connexion between the ionization and this rate of increase is in the case we are considering represented by a very simple equation. For if $n$ and $m$ represent respectively the number of negative and positive ions per unit volume, X the electric force, and $x$ the distance from the cathode

$$\frac{dX}{dx} = 4\pi(n-m)e \quad . \quad . \quad . \quad (24).$$

If the current $\iota$ is carried, as we have supposed, by the electrons, $neu = \iota$, where $u$ is the velocity of the electron, and if we neglect the current carried by the positive ions, then when things have reached a steady state the number of positive ions produced in any region per second must equal the number which disappear owing to recombination. Hence, if $q$ is the rate of ionization, $\alpha$ the coefficient of recombination, $q = \alpha mn$ or $m = q/\alpha n$. Hence we see that (24) is equivalent to—

$$\frac{dX}{dx} = \frac{4\pi\iota}{eu} - \frac{4\pi q e u}{a\iota} \quad . \quad . \quad . \quad (25).$$

Thus as long as $q$ vanishes, $dX/dx$ is positive, but as soon as $q$ becomes finite the rate of increase will be retarded; as X increases $q$ increases, and when $e^2qu^2 = a\iota^2$, $dX/dx$ will vanish; but though X reaches its greatest value at this point, the values of $u$ and $q$, which depend on the energy acquired by the electron, will continue to increase beyond it. For the energy acquired by an electron depends on $\int X dx$, taken over a distance measured by the free path of the electron; at low pressures this may be a centimetre or more, and the place where $\int X dx$ is a maximum will be beyond that where X is a maximum by a length of this order. Thus after X has reached its maximum $u$ and $q$ will increase and $dX/dx$ will become negative, so that X will diminish; the diminution in X will ultimately produce a diminution in $\int X dx$ and also in $u$ and $q$; the rate of decrease will slow down; X will attain a minimum, and begin to increase again when similar changes will be repeated. Thus the curve which represents the relation between X and $x$ will resemble fig. 14, giving alter-

nate maxima and minima for the value of $x$. Thus $\int X dx$, the energy acquired by an electron, will vary periodically along the path of the discharge. There are two values of this energy which are of special importance in connexion with discharge through gases, one the ionizing potential we have already referred to, the other, sometimes called the "radiation potential," is the energy which the electron must possess to make the gas luminous. The radiation potential is less than the ionizing potential, and electrons with energy between these potentials will make the gas luminous but will not ionize it. Thus the molecules of the gas will give out light but will not be charged. When the energy of the gas exceeds the ionizing potential the luminous molecules are or have been charged. If the variations in the energy along the line of discharge are large enough to make it sink below the radiation potential, then along the discharge we shall have:—(1) places where the energy is below the radiation potential,—these will be dark; (2) places where the potential is between the radiation potential and the ionizing potential,—the molecules here will be luminous and uncharged and will, therefore, not move under the electric field; (3) places where the molecules are luminous and charged,—these molecules will move down the tube towards the cathode with the velocity which the positive ion acquires under the electric field. This velocity, when the pressure is low and the field several volts a centimetre, as it is in the positive column, may be many thousand centimetres per second. Place (1) corresponds to the dark parts of the striations, (2) to the stationary luminous parts, while (3) is the origin of the striations moving down the tube observed by Wulner, Spottiswoode, Aston and Kikuchi.

*Cathode Rays.*—In 1859 Plücker observed on the glass of a highly exhausted tube in the neighbourhood of the cathode a

bright greenish yellow phosphorescence, which changed its position when a magnet was brought near to it. About 10 years afterwards Hittorf showed that a solid body placed between a pointed electrode and the walls of the tube cast a well-defined shadow of such a shape as to show that the agent producing the phosphorescence travels in straight lines at right angles to the surface of the cathode. The name "cathode rays" for the cause of the phosphorescence was introduced by Goldstein, who made many important investigations on their properties. The opinion held by Goldstein and generally in Germany was that cathode rays were waves in the ether. Varley and Crookes advanced the view that they were electrified molecules shot off at right angles to the cathode. The discovery by Hertz that the cathode rays could pass through thin layers of gold leaf was difficult to reconcile with this view. The evidence in favour of the cathode rays being electrified particles was much increased by Perrin's discovery that when a pencil of the rays entered the opening in a Faraday cylinder they gave a negative charge to the cylinder. One difficulty which had been urged against the rays being negatively electrified, viz. that, though they were deflected by a magnetic force, an electric force produced no effect upon their path—was removed by J. J. Thomson, who showed that the absence of deflection was due to the gas in the tube acting as a screen and protecting the particles from the electric force. As the gas in the vacuum tube is a conductor of electricity the rays move inside a conductor of electricity, and so will not be affected by an external electrified body. Thomson showed that when the vacuum was very high, so that there was but little gas in the tube, the cathode rays were deflected by an electric and magnetic field, and that the direction of the deflection indicated a negative charge on the particles. The measurement of the deflection by known electric and magnetic forces led to a determination of the mass of the particles which carried the charge, and showed that these particles were not atoms or molecules but something with a mass not one-thousandth part of the mass of the lightest atom known, that of hydrogen.

The deflection due to electric and magnetic forces can be calculated as follows. Suppose that the particles are travelling horizontally between two parallel horizontal metal plates A, B, maintained at a constant difference of potential, there will be a vertical electric force F acting between the plates, and if the axis of $y$ is vertical the equation of motion of the electrified particle when it is between the plates is

$$m\frac{d^2y}{dt^2}=Fe.$$

If $y$ and $\frac{dy}{dt}$ are both zero when the particle enters the region between the plates, then, when it leaves this region, after a time—

$$y=\frac{1}{2}\frac{Fe}{m}t^2 \text{ and } \frac{dy}{dt}=\frac{Fe}{m}t.$$

Since the electric force is at right angles to the direction of motion of the particles, $v$ the velocity of the particles will not alter, and if the deflection is small, $t=l/v$ where $l$ is the length of the plates. Thus—

$$y=\frac{1}{2}\frac{Fe}{m}\frac{l^2}{v^2} \text{ and } \frac{dy}{dv}=\frac{Fe}{m}\frac{l}{v}.$$

Suppose the particles strike a photographic plate or a screen covered with a phosphorescent substance at a distance L from the end of the plates, the $y$ displacement at this plate produced by the electric force is given by the expression—

$$y=\frac{1}{2}\frac{Fe}{m}\frac{l^2}{v^2}+\frac{Fe}{m}\frac{lL}{v^2}=\frac{Fel}{mv^2}\left(\frac{l}{2}+L\right).$$

*Magnetic Deflection of the Rays.*—If the rays go through a uniform magnetic field of length $l$ and strength H, then if the magnetic force is vertical the force acting on the moving particles will be Hev, and will be at right angles to the magnetic force and also to the direction of motion of the rays; i.e. it will be at right angles to the plane of the paper; if $s$ is the displacement of the particle in this direction—

$$m\frac{d^2s}{dt^2}=Hev.$$

From this we see that the value of $s$ at the screen is given by

$$s=\frac{Hel}{mv}\left(\frac{l}{2}+L\right).$$

Hence

$$m\frac{y}{s}=\frac{Hv^2}{F}\left(\frac{l}{2}+L\right) \quad (26)$$

and

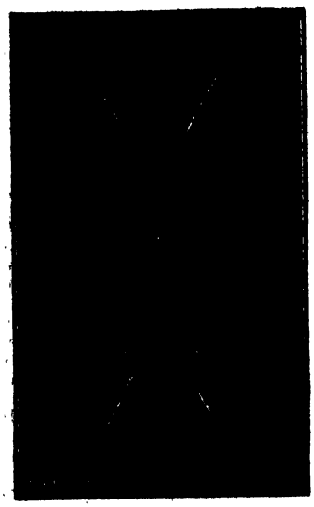
$$\frac{e}{m}=\frac{s}{y}\frac{F}{H^2v} \quad (27)$$

Thus the measurements of $y$ and $s$, the electric and magnetic deflections, give the values of $e/m$ and $v$.

The expressions for $y$ and $s$ have been obtained on the supposition that the electric and magnetic fields acted one at a time and not simultaneously. If, however, $y$ and $s$ are small, their values will not to a first approximation be altered if the electric and magnetic deflections occur simultaneously. Thus by making the cathode rays pass through superposed electric and magnetic fields, $e/m$ and $v$ can be got with one exposure by measuring $y$ and $s$ on the screen or photographic plate.

Since from the above equation (26) $m/y$ is constant as long as $e/m$ is constant, we see that all the particles of the same kind, whatever their velocity, would strike the screen or plate on a parabola, and that if the rays were a mixture of particles of different kinds each kind of particles would trace out a different parabola. Since $s/y$ only depends upon $v$, all the particles moving with the same velocity will strike the screen or plate in a straight line.

The determination of $e/m$ for the cathode rays led to results of fundamental and far-reaching importance, for it was found that all the cathode rays had the same value for $e/m$, and that moreover while for a charged atom of hydrogen in liquid electrolytes $e/m$ was equal to $10^4$, when $e$ was measured in electromagnetic units, the value of $e/m$ for the particles in the cathode rays was considerably more than one thousand times this value. Thus if $e$ were the same for the particle as for the hydrogen atom (and we shall see later that this is the case), the mass of the cathode particle is only [illegible] of that of an at[illegible]s which hitherto had been recogni[illegible]ever metal might be used for the ca[illegible]s in the discharge tube, the value [illegible]e particles must have come eithe[illegible] follows that the particles of the [illegible] the atoms of all the chemical ele[illegible] electrons."



After the elec[illegible]he cathode rays, they were soon d[illegible]ons and found to be of very wide-[illegible]mple, it was found that streams of [illegible]scent metals, the rate of emissio[illegible]the temperature. This has receive[illegible]plication in what are known as "[illegible]rrent from a hot cathode passes t[illegible]uum is so perfect that the gas tak[illegible] current, in some cases amounting[illegible]irely by electrons. Lenard found th[illegible]exposed to ultra-violet light. Th[illegible]ys strike against matter, and by [illegible]d of the electrons ejected either b[illegible]n rays does not depend upon the[illegible]y upon the wave length. The en[illegible] = $kn$ where $n$ is the frequency of[illegible]tant.

Since the cat[illegible]ic and magnetic forces proportio[illegible]orces, we can use the deflection of the rays as a measure for electric and magnetic forces. As these rays have practically no inertia they are especially adapted to measure very rapidly alternating forces which could not be detected by any index having an appreciable mass. The cathode ray oscillograph, an instrument by which electric and magnetic forces are measured by the deflection of cathode rays, has already been used in many investigations, and is a very important aid to research. Another property of cathode rays is that when they strike against matter they generate Röntgen rays, the hardness of the latter increasing with the speed of the former.

*Positive Rays.*—Goldstein discovered in 1886 that, if the cathode on a highly exhausted tube was perforated, bundles of a luminous discharge streamed through the aperture into the space behind the cathode. The colour of this discharge depends upon the gas in the tube; thus in hydrogen it is rose colour, in air, yellowish. The colour of the light due to these rays is not the same as that produced when cathode rays pass through the gas. In some cases the difference is very striking; thus in neon the light due to the cathode rays is pale blue, while the discharge which streams through the cathode is a gorgeous red. Goldstein called the rays which stream through the hole in the cathode *Kanalstrahlen*; but as they have been proved to consist of positively charged particles it seems more natural to call them "positive rays." These rays produce phosphorescence when they strike against glass and many other substances, though the phosphorescence is generally of a different colour from that produced by cathode rays. They also affect a photographic

plate. It was at first thought that the positive rays were not deflected by a magnet, as magnetic forces which produced large deflections of cathode rays had no appreciable effect upon positive ones. Wien showed, however, by using very strong magnetic fields, that they could be deflected, and that the direction of the deflection indicated that they carried a charge of positive electricity; they can also be deflected by electric forces.

By measuring the deflection provided by electric and magnetic fields we can determine the value of $e/m$ for the particles which constitute the rays. The result is of great interest. Instead of, as in the cathode rays, $e/m$ having the same value for all the carriers, we find that $e/m$ has many different values separated by finite intervals; and instead of $e/m$ being equal to $1{\cdot}78 \times 10^7$, as in the cathode rays, we find the greatest value of $e/m$ is $10^4$, which is the same as its value for a charged hydrogen atom. The values found for $e/m$ depend on the gases in the discharge tube; the outstanding result is that all these values of $m$ correspond to masses of atoms or molecules of the chemical elements or compounds. Thus while the determination of $e/m$ for the cathode rays shows that in a gas at a very low pressure the carriers of the negative electricity are all of the one type, being electrons whose mass is exceedingly small compared with that of any atom, the determination of $e/m$ for the positive rays shows that the carriers of the positive electricity are of many different types; and that all these types correspond to atoms or molecules of the chemical elements or compounds. It has already been shown that if charged particles, after passing through electric and magnetic fields, are received on a screen or photographic plate, all particles, for which $e/m$ is the same, strike the plate on a parabola, and that for each different value of $e/m$ there is a separate parabola.

These parabolas are shown in fig. 15, which is a reproduction of a photograph made by allowing the positive rays in a tube containing gases liberated by heating a certain mineral to strike against a photographic plate; taken from the top downwards they correspond respectively to the atom of hydrogen, the molecule of hydrogen, the atom of helium, the atom of carbon with two charges, the atom of nitrogen with two charges, the atom of oxygen with two charges, the atom of carbon with one charge, the atom of nitrogen, the atom of oxygen, the molecule of water, the molecule of CO and that of $N_2$ (these form one parabola), the molecule of oxygen, the molecule of $CO_2$ and the atom of mercury. We find that many of the atoms can carry more than one charge, for when we find a parabola corresponding to one value of $e/m$ we frequently find another corresponding to twice this value; thus carbon, nitrogen, and oxygen occur very frequently with two charges, other atoms such as argon with two and three charges, while mercury atoms have been detected with 1, 2, 3, 4, 5, 6, 7 charges. It is significant that the atom of hydrogen never occurs with more than one charge. Multiple charges generally occur on atoms but not on molecules; there are, however, some molecules such as CO on which double charges have been found. Some of the positive particles, after passing through the hole in the cathode, lose their positive charge and become uncharged, and some of these neutral particles acquire a negative charge; thus mixed with the positively electrified particles there are some negatively electrified ones. This power of acquiring a negative charge is confined to certain atoms; thus while the atoms of hydrogen, carbon, oxygen, fluorine occur with a negative charge, the atoms of nitrogen, helium, argon and neon do not. It is exceptional for a molecule to acquire a negative charge, the molecules of oxygen and carbon, however, can do so. The equation of a parabola formed by a particle on the photographic plate has already been given—

$$x^2 = \frac{e}{m} y C$$

where $x$ is measured parallel to the displacement due to the magnetic field and $y$ to that due to the electrostatic. C is a quantity which depends on the strength of the electric and magnetic fields and on the position of the photographic plate. If, as in fig. 16, we draw a

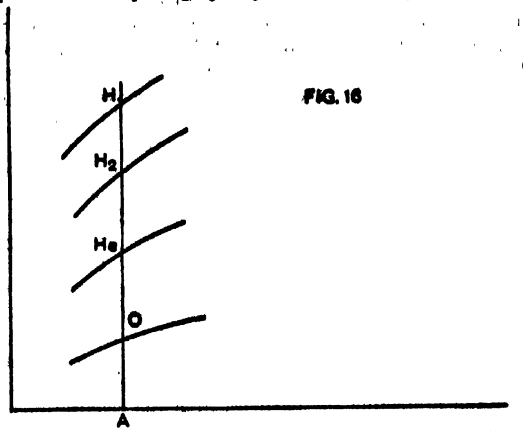


FIG. 16

line parallel to the axis of $x$, the intercept made by a parabola on this line will be proportional to $(e/m)^{\frac{1}{2}}$; thus, if the top parabola is due to the atom of hydrogen, the next to the molecule of hydrogen, the third to the atom of helium and the fourth to that of oxygen, the intercepts AH, $AH_2$, AO are in the proportion of $1, 1/\sqrt{2}, 1/4$. Thus by comparing the intercept made by any parabola X with that made by the parabola due to the hydrogen atom we can find the molecular weight of the substance producing the parabola X.

*Positive Rays as a Method of Chemical Analysis.*—Since from the measurement of the positive ray photographs we can determine the molecular weight of the gases in the discharge tube, we can analyze a gas by putting a small quantity of it in a discharge tube and taking a photograph of the positive rays. It is thus a method of chemical analysis, and its application has already led to the detection of several new substances. In fact, though it has only recently been introduced, more substances have been discovered by this method than have ever been discovered by spectrum analysis. The method has many advantages. In the first place only a very minute quantity of the gas is required; a small fraction of a cubic centimetre of gas at atmospheric pressure is all that is required to fill the discharge tube at the pressure at which the positive rays are produced. Again, the method is very sensitive, as it will detect the presence of a gas which only forms a small percentage of the gas in the tube. The method not only detects the presence of the gas, but at the same time determines its molecular weight. It indicates, if the gas is an element, whether it is monatomic or diatomic; for if it is diatomic it will give rise to two parabolas, one due to the atom, the other to the molecule. The absence of double or negative charges will suggest that it is a compound and not an elementary gas. The only ambiguity is that it does not distinguish between two substances of the same molecular weight; thus $CO_2$, and $N_2O$ give the same parabolas, as also do CO and $N_2$: we can often, however, remove this ambiguity by putting substances in the tube which would absorb one gas and not the other, and testing whether or not this has removed the parabola.

*Use of Positive Rays to Determine Atomic Weight.*—The measurement of the parabolas give, as we have seen, the atomic weight of the elements producing them; they can therefore be used to determine the atomic weight of elements which can be introduced in a gaseous state into the discharge tube. This method has the great advantage that the presence of impurities does not affect the result. Mr. Aston has lately, by the use of a positive-ray method for determining atomic weights, found the very important fact that, if oxygen is taken as 16, the atomic weights of the elements with the exception of hydrogen are represented by whole numbers. Thus in working with chlorine he found no substance with an atomic weight of 35·4, but two

substances with atomic weight of 35 and 37 respectively; he regards these substances as identical in chemical properties and inseparable by chemical reactions, and ordinary chlorine as a mixture of about 3 parts of ($35^3$) and one part of ($37^1$). Mr. Aston, by the method of positive ray analysis, has discovered isotopes of boron, silicon, bromine, krypton, xenon and mercury.

*The Charge of Electricity Carried by Gaseous Ions and Electrons.*—The deflection of cathode and positive rays by electric and magnetic forces supplies a method for finding the value of $e/m$; for the determination of $e$, the charge on an ion, other methods have to be employed. One such method used by J. J. Thomson is based on the important investigations of C. T. R. Wilson on the effect of ions on the deposition of clouds and fogs from supersaturated air. If dust-free air saturated with water vapour is suddenly cooled by expansion, no cloud or fog is deposited unless the supersaturation due to the cooling is very large. C. T. R. Wilson found that if ions are present in the gas they act as nuclei round which drops of water are deposited with a supersaturation much below that required for gas free from ions. A beautiful application of this is the detection of the path of an $\alpha$ particle from a radioactive substance. The $\alpha$ particle produces by collision ions all along its path; if the damp gas through which the particle is passing is suddenly cooled by expansion, drops of water will deposit on the ions and thus mark out the path of the particle. One of Mr. Wilson's photographs of such a path is shown in fig. 17. Mr. Wilson found that less supersaturation is

required to deposit water on negative than on positive ions. This result can be applied to find the number of ions in a moist gas, for if the gas is suddenly expanded by an amount sufficient to deposit drops on ions, but not sufficient to produce condensation in their absence, then each ion may be made the centre of a drop, and the problem of counting the ions is reduced to that of counting the drops.

We can calculate the amount of water that will be deposited by any given expansion of the air; hence, since we know the volume of the water we can determine the number of drops if we know the volume of a single drop. Observation of the rate at which a drop falls under gravity will give the size of the drop, for Stokes long ago showed that the velocity of a rain drop falling under gravity is given by the equation $v=\frac{2}{9}g\frac{a^2\rho}{\mu}$; when $v$ is the velocity of the drop, $a$ its radius, $\mu$ the viscosity of the gas, $g$ the acceleration due to gravity, and $\rho$ is the density of the gas. It has been found that with the exceedingly fine drops formed round ions where the radius of the drop is comparable with the free path of the molecules of the gas, the velocity is greater than that given by the above, equal in the proportion of $\left(1+\frac{C}{pa}\right)$ to 1, when C is a constant, and $p$ the pressure. But though this correction makes the relation between $a$ and $v$ a little more complicated it still enables us to determine $a$ when $v$ is known. Thus the radius, and therefore the volume, of the drop can be determined, and from this, as we have seen, we can deduce the number of ions.

Let $n$ be the number per unit volume; then if a current of electricity is sent through the gas by an electric force X, the current passing through unit area will be $neU$ when $U$ is the mean velocity of the positive and negative ions under the force X. We know that it is proportional to the force and for a force of one volt per centimetre is 1·5 cm./sec.; and hence when X is known $U$ is known, the current $neU$ can be measured, and hence $ne$ deduced; as $n$ has been found by the drops, the value of $e$ can be determined immediately. This was the method used by J. J. Thomson; a simpler method used afterwards by H. A. Wilson was to get drops round the negative ions alone by using an expansion that would deposit moisture on negative but not on positive ions. He then showed the rate of fall of these drops, first under gravity alone, and then under a vertical electrical force X, acting on the drop in the same direction as gravity. Thus, when the electric field is acting, the force on the drop is

$$Xe+\frac{4}{3}\pi\rho a^3 g,$$

and when it is off the force is only $\frac{4}{3}\pi\rho a^3 g$. Thus, if $v_1$, $v$ are respectively the velocities of the drop when the field is on and off,—

$$\frac{Xe+\frac{4}{3}\pi\rho a^3 g}{\frac{4}{3}\pi\rho a^3 g}=\frac{v_1}{v}$$

$$\text{or } Xe=\frac{4}{3}\pi\rho a^3 g\,\frac{(v_1-v)}{v}.$$

From $v$, the rate of fall when the field is off, we can calculate as before the radius of the drop, and from the preceding equation we can determine $e$. Millikau, who has made most extensive and accurate investigations on the value of $e$, used a modification of the preceding method. Instead of producing water drops by expansion on the ions, he obtained, by means of a sprayer, minute drops of oil; he observed the motion of one of these under an electric field in a gas which was subject to some ionizing agent, and from time to time an ion would strike against the drop and alter the charge; this would alter the velocity, and from the alteration of the velocity he could by a formula similar to that just given calculate the charge communicated to the drop by the ion. The value obtained for $e$ by this method is, in electrostatic units,—

$$e=4{\cdot}77\times10^{-10}.$$

From the value of $e$ we can obtain Avogadro's constant, the number of molecules in a cubic centimetre of gas at 0c and 760 mm. pressure. For Townsend has shown that $Ne=P\frac{u}{XD}$ where P is the pressure when the number of molecules is N, $u$ the velocity of the ion when the force is X, and D the coefficient of diffusion of the ion into the gas. Townsend measured D, and found that the value of Ne determined by this equation was, within the limit of errors of experiment, equal to NE as determined by experiments on the quantities of hydrogen liberated by electrolysis. E is here the charge carried by an atom of hydrogen in the electrolysis of liquids. Thus the charge on the gaseous ion is equal to that on the liquid ion. Since one coulomb deposits 1·11827 milligrams of silver, and the atomic weight of silver is 108 and the density of hydrogen $8{\cdot}987\times10^{-5}$ at 0c, $NE=1{\cdot}290\times10^{20}$, and as $e=4{\cdot}77\times10^{-10}$, $N=2{\cdot}7\times10^{19}$. The number of molecules in a gramme molecule of any substance is $6{\cdot}06\times10^{23}$.

Thus the study of the electrical property of gases has given the most accurate values available of two of the most important constants connected with the constitution of matter. By studying electrified atoms and molecules, we have been able to determine their masses and their properties with an accuracy far beyond that attainable by any method which can be used when they are in the normal state. (J. J. T.)

**GASQUET, FRANCIS AIDAN** (1846– ), Roman Catholic cardinal and historian, was born in London Oct. 5 1846. He was educated at Downside College, Bath, afterwards becoming superior of the Downside Benedictine monastery (1878–1885). He was created cardinal in 1914. He has produced various works on mediaeval church history and liturgies, among them being *Henry VIII. and the English Monasteries* (1888–9); *A Short History of the Catholic Church in England* (1905); *Parish Life in Mediaeval England* (1906) and *The Bosworth Psalter* (1908).

**GAUL, GILBERT WILLIAM** (1855–1919), American painter (*see* vi. 532), died in New York Dec. 22 1919. He was awarded a gold medal at the Appalachian Exposition, Knoxville, in 1910.

**GAUTSCH-FRANKENTHURN, PAUL, Freiherr von** (1851–1918), Austrian prime minister, was born at Vienna Feb. 26 1851. He was director of the Theresa academy from 1887 to 1889, and Minister of Education from 1895 to 1897 and from 1899 to 1905. He was three times prime minister: first from

1897 to 1898, when he revoked the language ordinances made by Badeni; again from 1904 to 1906, when he prepared the way for universal suffrage; and for the last time from June to Oct. 1911. He died on April 30 1918.

**GEDDES, SIR AUCKLAND CAMPBELL** (1879– ), British man of science, administrator, and diplomatist, was the son of Auckland Campbell Geddes of Edinburgh and the younger brother of Sir Eric Geddes, and was educated at George Watson's College, Edinburgh, and Edinburgh University. He studied medicine, qualified as a practitioner, was at the London hospital for a time, and later studied at Freiburg. He was a demonstrator and professor of anatomy first at Edinburgh, then at the Royal College of Surgeons, Dublin, and afterwards at McGill University, Montreal. He had also military experience, first in the South African War, and afterwards in the World War from 1914–6, becoming eventually a brigadier-general in the Territorial Force. At the outbreak of war he was still at McGill University; but in 1916 he was brought into the War Office as Director of Recruiting. The remarkable efficiency of his work in this capacity caused him to be appointed to succeed Mr. Neville Chamberlain in Aug. 1917 as Minister of National Service. This was one of the new ministries instituted by Mr. Lloyd George, with a view to the more energetic prosecution of the war. The great problem was to utilize the man-power and woman-power of the country to the best advantage. Sir Auckland Geddes outlined his policy in speeches at Edinburgh on Oct. 3, at Nottingham on Oct. 9, at Plymouth on Nov. 12, and at the Aldwych Club on Nov. 14. Instead of following Mr. Chamberlain's plan of building up a great department, he proposed to utilize existing machinery as far as possible. He contemplated a system of industrial coöperation, and determined to carry out the necessary transference of labour by means of labour's own organizations. More men were wanted for the shipyards, the production of steel, the making of aerodromes, and the production of aircraft and aero engines. To get them he proposed to use the employment exchanges, the trade unions, and the employers' federations. He appealed for volunteers for seasonable occupations like haymaking and harvest, and said that the waste of power in domestics, chauffeurs, and gardeners must stop. He made a special appeal to young, healthy, middle-class femininity. He instituted four grades of physical fitness. He said that the need of men and women for the army must be obtained by a drastic comb-out of individuals. He condemned extravagance on luxury, such as women's clothes. His department made a card index of the whole of the army at home, so as to get back into civil life men unfit for active service but fit for industrial occupations. His object was to ensure the maximum effort of the country for the following spring, when the strain would be the greatest.

A seat in Parliament was found for Sir Auckland at Basingstoke, and unlike some of the eminent practical men whom Mr. Lloyd George introduced from the outside into his administration, Sir Auckland had little difficulty in accommodating himself to parliamentary life. He introduced in Jan. 1918, and carried through Parliament in Feb., a bill the chief object of which was to call up from civil employment a number of young men who had hitherto been exempt from military service. He secured the coöperation of the trade unions in general, and even eventually of the Amalgamated Society of Engineers, which had hitherto proved recalcitrant. It was largely due to his efforts that the man-power and woman-power of the whole country was so completely thrown into the prosecution of the war as to make the victory of 1918 possible. In Nov. he became President of the Local Government Board and Minister of Reconstruction, and in the following May President of the Board of Trade. In this latter capacity he began the removal of the barriers to British trade which the war had necessarily set up, and he had to deal with the difficulties which immediately arose in the coal industry. He pointed out that the shortening of the working-day and the slackness of production had resulted in a deficiency of nearly 50 millions of money, that England could not get back to her industrial position before the war, unless the work of the country was done, and it was not being done. He had to increase the price of coal by 6d. a ton in the summer; but in Nov., as the result of a conference with the Labour party, he announced that the British consumers ought to profit by the profits on export coal, and reduced the price of domestic coal by 10s. In 1919 an opportunity was afforded him to return to academical life by his selection to succeed Sir W. Peterson as principal of McGill University. He accepted the appointment, subject to its not being operative until he could be spared from his work at the Board of Trade on account of the coal crisis in England. But the delay so caused prevented his taking up the appointment, and in the spring of 1920 the Government prevailed on him to accept the post of British Ambassador at Washington, Gen. Sir Arthur Currie being made principal of McGill in his stead. It was thought that his combination of academical and intellectual interests with military and administrative experience, together with his knowledge of, and affection for, Canada, gave him peculiar qualifications for the Washington Embassy. He had, moreover, married in 1906 an American wife, Isabella Gamble, daughter of W. A. Ross of New York, by whom he had four sons and one daughter. He was made a K.C.B. in 1917.

**GEDDES, SIR ERIC CAMPBELL** (1875– ), British man of business and politician, born in India Sept. 26 1875, was the son of Auckland Campbell Geddes of Edinburgh and the elder brother of Sir Auckland Campbell Geddes. He was educated at Oxford Military College and Merchiston Castle school, Edinburgh. He gained business experience lumbering in the southern states of America, and he afterwards was connected with railways [illegible] the Baltimore & Ohio system in the United States, and [illegible] Rockland and Kennebec in [illegible]. Returning to England, he joined the North Eastern Railway Co., under Sir George Gibb, [illegible] having succeeded him in [illegible] was himself the general manager of that line when the Great War broke out in 1914. He was [illegible] business men whom Mr. Lloyd George, on becoming Minister of Munitions, enlisted in Government employ. He became deputy director-general of munitions supply 1915–[illegible] and his powers of administration so impressed the minister [illegible] with the conduct of the [illegible] that, when in 1916 the question of [illegible] behind the lines of the British army in France became urgent, and Sir Douglas Haig asked for the help of an expert, he was appointed, though a civilian, director-general of military railways and inspector-general of [illegible], with the rank of lieut.-major-general. Under him, [illegible] railway managers whose services were enlisted, the British lines of communication in the latter part of the war were brought into a high state of efficiency. He was knighted in 1916 and in 1917 he was created K.C.B. and G.B.E., being transferred to the Admiralty in May of that year as controller, with the honorary rank of vice-admiral, in order to develop and utilise the whole of the shipbuilding resources of the country and concentrate them under one authority. So highly did Mr. Lloyd George value his work that when Sir Edward Carson resigned the office of First Lord of the Admiralty a couple of months later, the Prime Minister selected Sir Eric Geddes, in spite of his having no parliamentary experience, to succeed him. A seat in the House of Commons was provided for the new minister at Cambridge (town). He held office at a time when the unrestricted German submarine warfare was levying a heavy toll on the British mercantile marine. He informed the House of Commons in March 1918 that the monthly output of British shipbuilding yards would have to be nearly doubled before the monthly rate of sinking was made good; and he appointed Lord Pirrie, the great Belfast shipbuilder, as controller-general of merchant shipbuilding. In Oct. he went at the head of a naval mission to the United States. After the Armistice Mr. Lloyd George availed himself of Sir Eric's powers as an organizer by appointing him to coördinate Government departments in regard to demobilisation. His success in these varied tasks was rewarded in Jan. 1919 by the G.C.B. The Prime Minister's programme for the election of Dec. 1918 included "the development and control . . . of the railways and the means of communication," and

"a systematic improvement in the transport facilities of the agricultural areas." For the purpose of carrying out this policy, Sir Eric left the Admiralty when the ministry was reconstructed in Jan. 1919 in order to organise and preside over a new Ministry of Transport. Until the bill constituting it was passed in the summer, he held Cabinet office without portfolio. The measure, which was opposed in both Houses as tending unduly to nationalization, gave the minister control of railways, roads, canals and docks. The constitution of the new ministry subsequently aroused severe criticism on account of its extravagant scale when in 1920–1 all eyes were fixed on the need for economy; and in view of the contemplated handing back of the railways from State control to the companies in the autumn of 1921, it became understood that its future was very doubtful, and that Sir Eric himself had no desire to continue in public life after that event. A bill for regrouping the railways was introduced by him in the spring of 1921. Sir Eric Geddes married in 1900 Gwendolen, daughter of the Rev. A. Stokes, and had three sons.

**GEIKIE, JAMES** (1839–1915), Scottish geologist (*see* 11.553), died at Edinburgh March 1 1915.

**GENETICS.**—This term was proposed at the third conference on hybridisation 1906 to denote the study of heredity and variation. In that sense it has been generally adopted, and by extension is understood to include the physiology of reproduction and the art of breeding. Though such inquiries have been pursued from the earliest times, the development of a special branch of science relating to them is recent. The primary incentive was the hope that by applying accurate methods of observation and experiment to the course of heredity and variation a more precise knowledge of evolutionary processes might be acquired. Modern theories of evolution are based on the assumption that species have arisen by descent with modification, and that the constancy and diversity which living things manifest in their reproduction provide a sufficient basis for that conception. It is significant that as a result of the preliminary work done under the new inspiration attention has been largely diverted from these more philosophical aims. Beliefs current among naturalists, especially as to the nature and incidence of variability, were at once found to be widely incorrect. The scope and character of these discoveries are referred to below. Their immediate consequence has been that the development of evolutionary theory is tacitly suspended or postponed, and activity is concentrated on the exploration of genetical physiology, the theoretical evaluation of the knowledge thus gained being relegated to the future.

In these researches several methods of investigation are available. Modern genetics began with an attempt to observe empirically the course of contemporary variation from type; but though observations of this class have proved valuable in a preliminary survey, and have often been of use as indicating material for more prolonged investigation, the main advances have been accomplished by either (1) experimental breeding or (2) cytology. Important sidelights on genetical problems have also been obtained through the study of developmental mechanics (*Entwicklungsmechanik*) by experimental methods.

(1) *Experimental Breeding.*—The great stimulus to this method of research was given by the rediscovery in 1900 of Mendel's paper (*see* 18.215). Heredity, long regarded as a fortuitous and seemingly lawless phenomenon, was proved to follow regular principles which could in great measure be ascertained by experiments properly planned. A vast field was at once thrown open for investigation. Mendel's success was made possible by his genius for simplification. Working with peas he made crosses between distinct varieties and watched the descent of their numerous characteristics, fixing his attention on each separately, and disregarding other differences. He then found that numerous distinctive features behaved in descent as if they were transmitted as units. These determining elements or units are referred to as *factors* or "genes" (a term especially used by American writers, the equivalent of Johannsen's *Genen*). The differences determined by these factors can commonly be shown to be treated in heredity as pairs of alternatives or opposites, such as tall and short, coloured and colourless, hairy and smooth, each germ-cell being usually pure in respect of one or other of the contrasted characteristics. This is the principle of *allelomorphism*, and the members of such pairs are called *allelomorphs*. The zygote, formed by two germ-cells united in fertilization, may be made up of two germ-cells alike in respect of any given pair, in which case it is said to be *homozygous* in that respect, or it may be a *heterozygote* if the uniting pair of cells are unlike. Before the germ-cells of the heterozygote are formed a process of *segregation* occurs, and there is a dissociation between the opposing elements introduced at fertilization, such that the resulting germ-cells are again in normal cases pure in regard to each allelomorph.

After the rediscovery of Mendel's work, progress was rapid, and it was soon found that similar principles of descent apply to a great range of characteristics by which living things are distinguished. The number of forms of life studied is now very large, and includes most of the kinds of plants and animals which are readily amenable to experiment or observation. Man is evidently no exception, and we already know that certain features of human coloration, especially of hair and eyes, and several congenital abnormalities are transmitted according to the Mendelian scheme, some being dominant, others recessive.

Scarcely any satisfactory opportunities for studying the genetics of the lower plants (ferns, mosses, Algae, etc.) have yet occurred, but one example has been described in a unicellular Alga (Pascher). Of the features by which animals and plants are distinguished most have now been shown to be dependent on segregable elements. Reservation must be made in regard to differences which are simply quantitative, for there is a good deal of evidence suggesting that the elements by which size and weight are determined do not often form themselves into simple allelomorphic pairs. A similar doubt exists in regard to numerical or meristic distinctions.

Differences in instinct and other characters dependent on nervous mechanism are not, as such, distinct in their genetical behaviour, and some have been proved to depend on segregable factors or elements. In several breeds of fowls the hens are devoid of maternal instincts, and do not sit on eggs. This characteristic is recessive to the normal instinct, and segregation takes place in regard to it. The same is true of the pacing habit in horses as opposed to the trotting habit. The "waltzing" habit of certain Japanese mice is recessive to the normal, segregates from it and breeds true when it reappears. This example is interesting, since the abnormality is almost certainly a consequence of deformity in the semicircular canals of the ear.

As to the descent of the normal mental attributes of man little is known with accuracy, but several abnormalities of the nervous system are known to follow modes of descent which prove them to be subject to segregation. Feeble-mindedness is a recessive condition which breeds true. Paralysis agitans is also a recessive. Hereditary chorea descends as a dominant; colour-blindness and a form of night-blindness may also be termed recessive (*see* SIGHT). In heterozygous combination with the normal there is segregation, but the descent of these conditions is complicated by sex.

It will readily be understood that though the determining factors may be transmitted as units, the distinguishing characters of animals and plants must be often due to the association of many independent units. Of these some produce their effects separately; but not rarely, though independently transmitted, two or more unit-factors may be complementary to each other and combine to produce a joint effect, or "compound character" as it is sometimes called. Such complementary factors if separately present in the organism without their complement need not manifest their presence at all, and it is then only by breeding tests that their existence can be demonstrated.

Organisms may now be represented as aggregates of units which confer upon them their various attributes. The degree to which an organism may be thus resolved is as yet undetermined, but there is presumably a limit to the process, and it is natural to suppose that the detachable elements are implanted on a *basis* which for a given type is irreducible.

*Recension.*—Conceptions, formerly vague, now acquire an

exact meaning. For example, reversion or "throwing-back" to an ancestral form, previously regarded as a mere caprice of nature, can at once be perceived to be due to one of two definite causes which operate with regularity. The reversion is either (*a*) the reappearance of a recessive characteristic, or (*b*) it is the consequence of the reunion of complementary factors which, though both present together in the ancestor, had been separated by variation and transmitted in distinct strains. For example, when a red-haired child is born to dark-haired parents the fact proves that the two parents are heterozygous in respect of the recessive red, which reappears when two germ-cells carrying it unite in fertilization. Moreover, if the statistics of a considerable number of such families of children were collected and added together it would be found that the proportion of red-haired was approximately a quarter of the whole. The mere fact that one or both of the parents traces descent from a red-haired ancestor is not the *cause* of the reversion—for if either of the parents were homozygous in dark hair the red would not have reappeared.

The reversion to an actual or supposed ancestral form consequent on the meeting of complementary factors is less common in the ordinary practice of breeders, but is frequently seen in experimental crossing. When two white orchids crossed together give a coloured flower in $F_1$, or when a rose-combed fowl bred with a pea-combed bird gives chickens with the walnut comb of the Malay fowl, the production of the unexpected colour or structure is due to complementary action of two independent factors. But the old interpretation of the phenomenon as a consequence of such an ancestor having occurred in the pedigree is illogical and misleading. In the case of the walnut comb, for instance, it is quite possible that either or both of the parent breeds never had a Malay ancestor. The production of a new form by the meeting of complements should be regarded, like the properties of a chemical compound, simply as the empirical consequence of a certain combination of units, without reference to the previous history of those units.

*Purity of Type.*—Of greater importance, both theoretical and practical, is the fact that it is now possible to assign a precise meaning to this expression. To the pre-Mendelian evolutionist purity was always a matter of degree, which might be gradually and, as it were, asymptotically approached in successive generations of selection, but never actually attained. The practical breeder also has always regarded purity as a property necessarily dependent on a long course of selection. Purity is now seen to be the condition of the animal or plant which is formed by the union of gametes bearing identical units. In respect of any allelomorphic pair purity may thus be conferred, though in respect of other pairs of units the same organism may be impure, *i.e.* heterozygous, or, in ordinary parlance, cross-bred. This is the central fact of Mendelism, and on it Genetics is based.

The question of purity must therefore be considered separately for each pair of units. A thoroughbred horse, for example, may be pure in a number of characteristics which go to the making of the breed, but it may be impure in, say, colour. A chestnut horse, however, of whatever parentage, is pure-bred in colour, since that colour is the lowest of the series of horse colours, and chestnuts bred together give chestnuts only. By selection the likelihood of producing purity is increased, but, as will subsequently appear, no amount of selection can ensure purity. On the other hand, purity in respect of any character may be attained at once in any mating by which gametes of similar factorial composition happen to be brought together in fertilization. From this proposition the corollary follows that the combination of two strains pure in any given respect will give a family uniform as regards the character considered, and the uniformity of such cross-bred families, especially when one of the parents contains few dominant factors, is in practice one of the simplest and most convincing tests of purity.

*Genetic Analysis.*—By the institution of a series of crosses with varieties and study of the composition of the succeeding generations an *analysis* of the factorial constitution of a given type can be made. The numerical proportions or ratios in which the several combinations of characters are represented, the number of these terms in the series, and their respective genetical powers of transmission furnish the data from which the nature and number of the factors comprising the parental type may be determined. In the earlier article on Mendelism (*see* 18.115) some of the simpler ratios and their significance are explained, but examples of a much higher order of complexity are often encountered. The unravelling of these complications has led to some important discoveries. The many ways in which it may come to pass that two or more terms in a series of factorial combinations may be indistinguishable from each other cannot be enumerated here, but a knowledge of some of the more significant causes of disturbance of what may be called the normal ratios (9:3:3:1; 9:3:4; 27:9:9:9:3:3:3:1, etc.) is essential to a proper comprehension of Genetics.

*Cumulative Factors.*—From certain crosses (especially of cereals) into which only one pair of differences had apparently been introduced it was observed (Nilsson-Ehle; East) that the recessives reappearing in $F_2$ were only 1:15 instead of the usual 1:3. Investigation proved that from the dominant side *two* factors with identical functions, though belonging to distinct pairs, had been introduced. Consequently, among the dominants in $F_2$ were some containing both these factors and others having one only. Various results suggest that this multiplication, or better, *accumulation*, of similar factors is a phenomenon of common occurrence, and that the process may be extended in special cases.

*Inhibiting and Lethal Factors.*—Many factors act by producing a negative result, inhibiting the development of some character, the determining elements of which are present though their action is not perceptible or largely diminished. Of these the most easily demonstrable operate by inhibiting the formation of colour. The white pigment of the coats of animals and the feathers of birds, or of flowers, for example, is commonly due to the absence of the elements necessary for the formation of colour, but both in animals and in plants varieties have been found which are white, or nearly so, not through absence of pigment, but through the presence of factors which, in some way not yet defined, inhibit the production of the coloured pigments. From some matings a mixture of white individuals may be obtained, which to the eye look alike, or nearly so, though they represent various factorial terms and are genetically dissimilar. The process of inhibition may be carried much further, and there are well-established instances in which the animal or the plant cannot live if it is homozygous (containing two "doses," in popular terms) for a given factor. The classical instance of such *lethal* factors, as Morgan has called them, was met with in the breeding of yellow mice (Cuénot; F. M. Durham). Mice with yellow coats, bred together, give a majority of yellows, but always throw a proportion of some other colour—for example, chocolate or black. Since in mice yellow is a dominant, it is clearly caused by a factor which the gametes can carry. But the union of two gametes, both carrying this factor, does not give rise to a viable animal. It was suggested that two such gametes could not unite in fertilization, but later work has practically proved that these fertilizations occur and that the resulting embryo perishes at an early stage (Ibsen). The physiological action of the yellow factor in causing death is not known. In plants the "golden"-leaved varieties are comparable. They cannot breed true, but throw 2 yellow: 1 green. The purely yellow term is missing, and is clearly not viable (Baur). The suggestion has been made that the yellow factor acts not merely negatively by diluting the amount of chlorophyll, but by inhibiting its formation, probably producing a body with this specific power. This is the more likely since golden varieties in dull weather turn almost a full green, whereas in sunlight they bleach to a full yellow, the fact indicating that the production of the inhibiting body is promoted by sunlight. Two doses of this factor kill the plant altogether, probably during embryonic life.

*Linkage.*—At an early stage in these inquiries it was observed that factorial units belonging to separate allelomorphic pairs are not always distributed independently among the gametes of a heterozygote, but that some combinations occur regularly with a greater frequency than others. The next step was the discovery that this *linkage* depends on the association of the linked factors in the parent from which the heterozygote was formed. For example, if a form $AB$ is crossed with $ab$ the normal expectation is that the double heterozygote $AaBb$ will form gametes $AB$, $Ab$, $aB$, $ab$ in equal numbers; but if there is linkage between $A$ and $B$, then the parental combinations $AB$ and $ab$ will be more frequently represented in the gametic series than the other, or "cross-over" combinations, $Ab$ and $aB$. But if the original cross were in the form $Ab \times aB$, then the most frequent gametes will be $Ab$ and $aB$, the cross-overs, $AB$ and $ab$, being the rarer. This observation forms the starting-point from which modern genetical theory has been very largely developed. The terminology followed above is that introduced by T. H. Morgan, to whom progress has been especially due. It is sometimes convenient to distinguish the case in which the two dominants ($AB \times ab$) are introduced together by the parent as *coupling*, and the converse ($Ab \times aB$) as *repulsion*, but the physiological process is now recog-

mind as being clearly the same in both cases, and there is no difference in the numerical proportions in which the parental combinations respectively reappear. It should be observed that the factors thus linked have plainly no connexion with each other as regards the effects which they produce in the zygote, but may concern the most dissimilar characters. For instance, in the example first observed the linkage was that between the factor which makes the flower of the sweet pea blue or purple (as distinguished from red) and that which makes the pollen grains long (as distinguished from round). According as the proportion of cross-overs is small or large the linkage is more or less complete. If both parental and cross-over terms are equally common there is no linkage. The most satisfactory test of the linkage-ratio is obviously provided by breeding the double heterozygote (*Aa-Bb*) with the double recessive (*aabb*), and this mating should be carried out reciprocally since it is known that in plants (*e.g.*, *Primula sinensis*) the male and female sides of the same plant may show different degrees of linkage (R. P. Gregory), and that in animals (*e.g.*, *Drosophila* and the silkworm) crossing-over may be entirely absent in one sex though occurring in the other.

*Allelomorphism: Multiple Allelomorphs.*—Apart from linkage, segregation is always a separation of units affecting the same character, and from a very large range of observations it is possible to represent the distinction between the allelomorphic pair as one in which a *positive* element separates from a *negative*. In other words, allelomorphism may commonly be conceived as a difference which consists in the *presence* of something on the one side and its *absence* on the other. This conception is applicable whenever there is definitely pronounced dominance. It is natural that the characteristic which possesses dominance should be looked upon as due to the positive or present element, the recessive being the consequence of its absence. Nevertheless there is as yet no strict proof that this representation is physiologically correct. For since we know that many factors may operate by inhibition it is always possible to *invert* the conventional representation and, by putting negative for positive, to make a factorial scheme which equally agrees with the observed results. Conventionally, for instance, the tall pea is represented as either *TT* (homozygous) or *Tt* (heterozygous), the dwarf being *tt*, from which the positive element *T* tallness is absent. But we cannot positively declare that the dwarfs may not be *TT* homozygous in the presence of an inhibitor *T*, whereas the tall plants might be either *Tt* heterozygous or *tt* homozygous in respect of the absence of this inhibitor. The significance of this alternative mode of representation will be apparent when the application of factorial systems to evolutionary theory is attempted (*see* MENDELISM). But when the heterozygote is intermediate between the two homozygous forms the "presence-and-absence" method of representation cannot be applied with any confidence. From the existence of such cases and from certain other considerations it has been urged, especially by American geneticists, that the method of representation by presence-and-absence is incorrect, and that a negative allelomorph should be treated as a real entity. There is no valid means of deciding this question as yet. The probability is perhaps that the absence should always be regarded as relative only. As a mode of symbolic expression the representation of the two allelomorphs as differing quantitatively is often convenient, though certainly not universally applicable.

Allelomorphism is, as the term implies, a relation between two alternatives, and in any one zygote there can be no more than two. Nevertheless there are instances in which the same unit-factor enters into heterozygous combination with various alternatives in different zygotes, and each of these may thus be in allelomorphic relation with it. Alternatives composing such a group of possibilities have been termed by Morgan *multiple allelomorphs*, and this expression is commonly adopted. Its use, however, makes the application of the term "multiple" to "factors" in a totally different sense a probable source of confusion, and for this reason the word *cumulative* or some equivalent is there to be preferred, as suggested above. The distinctions which together make up a set of multiple allelomorphs may commonly be recognized as a series of *quantitative* differences, the character affected being throughout the series the same. One of the most familiar illustrations is provided by the degree of albinism in rabbits. The fully albino form is white with pink eyes, but there is a variety called Himalayan, which, though born white with pink eyes, acquires some chocolate pigment in certain parts. Himalayan is dominant to albino but recessive to the ordinary coloured types. If a coloured type is bred with Himalayan the heterozygotes so raised cannot, when interbred, throw albinos; nor can heterozygotes raised from coloured × albino throw Himalayans, even though the albino used as their parent had itself been extracted from Himalayans. The degree of albinism put in by the parents comes out in $F_2$ and in the same degree. Hence it is not possible from similar parents to breed all three kinds, but, on the other hand, each family can contain at most two of them.

This phenomenon can be interpreted in either of two ways. The Himalayan pattern may be regarded simply as a quantitative diminution or fraction of the sum total of colour needed to make the self-coloured type. The rat albino is thus produced by the absence of the whole unit needed *for* colour, and the Himalayan by the absence of part of this total. It is then obvious that the heterozygote, coloured × albino, could never produce a Himalayan unless the colour-complex broke up again *de novo*. But on the analogy of the behaviour of other colour patterns the self and the Himalayan might be conceived as each consisting of two units: one *for* colour and one a factor determining its pattern, intensity or distribution. If there were a very close linkage between each "pattern" factor and colour the observed facts could then be represented; but by continued breeding the supporters of this view would expect the missing cross-over eventually to appear as either a Himalayan associated with recessive albinos or an albino associated with recessive Himalayan. On the ground of simplicity the former view seems preferable. The significance of these two alternatives will presently appear.

More complex illustrations of these possibilities have been described by Nabours in certain grasshoppers (*Paratettix*). The species studied presents a long series of colour forms, and experimental breeding showed that with certain exceptions all the pure forms behaved as if allelomorphic to each other. In other words, whichever two pure forms *A* and *B* were crossed together, the $F_1$ generation was *AB* giving in $F_2$ a family approximating to 1*AA* :2*AB* :1*BB*. The whole series of colours is thus often described as a vast set of multiple allelomorphs. Nevertheless there are curious features in that case which raise a doubt whether this account is really correct. Many of the distinctions are plainly *quantitative* degrees in development of some one type of coloration which are, as might be expected, allelomorphic to each other (*cf.* the Himalayan rabbit); but among the elements comprising the total coloration of these grasshoppers there are several in which both the pigments and the positions they occupy are so distinct that the characters cannot easily be represented as determined by factors allelomorphic to each other. Only by a very loose application of the term colour can the distinctions be said to apply to the same character. Hence, in this hitherto generally accepted illustration it seems probable that, in so far as the distinctions are actually quantitative differences in one respect, true allelomorphism may be recognized, but that the appearance of an allelomorphism between factors of differing scope is more probably spurious, and referable to close linkage (*cf.* Haldane). No decision on this question can yet be made with any confidence.

*Allelomorphic Complexes.*—Among recent extensions of genetical theory none is more remarkable than the discovery that large and apparently miscellaneous groups of characters are sometimes governed by elements capable of segregating collectively as a single complex. Nevertheless, in the case of sex, we have long been familiar with one example. Since the distinction between the two sexes in many animals is known to behave in segregation as if it depended on a single Mendelian factor, we have to recognize that a number of distinctions of all kinds, structural and functional, may be treated in segregation as factorially single. In the special case of sex we know further that particular genetic elements may be detached from the complex (*e.g.* the elements governing spur and broodiness in fowls, the beard in man, etc.), though the possible limits of such disintegration are unknown.

Renner's experiments have shown that the inheritance of the protean variations of several Oenotheras is largely effected by the transmission of similar complexes. Each of these large composite factors or groups of factors (in so far as they prove to be divisible) may govern many characters of form, colour, habit, etc., and the whole group is transmitted as a single heritable entity. Similar discoveries will probably be made in regard to other forms. The details are beyond the scope of this article, but it may be remarked that these complexes in Oenothera supply one of the most striking illustrations of the phenomenon which may be called *unilaterality* (*see* "Somatic Segregation," *infra*) or the relegation of a factor or factors exclusively to one sex-side of a plant. For instance, whereas *Oenothera Lamarckiana*, the species which provided de Vries with his most celebrated but unsound evidence of mutation, can be proved to be a permanently heterozygous form having two complexes equally distributed in segregation to both the male and the female gametes, the species *biennis* and many more, though similarly heterozygotes of two complexes, in segregation pass the whole of the one complex into the male gametes and the whole of the other into the female gametes. The question whether the apparently simple factors which commonly behave as Mendelian units are capable of further resolution is of much theoretical importance in its bearing on the problem of the nature of variation. Such a complex factor as that which determines sex may evidently break up into simpler components, but for various reasons some geneticists incline to the belief that factors in general are permanent and irresoluble. Whenever a series in $F_2$ derived from two clearly distinct and true-breeding types consists of a number of intergrading forms it is possible to interpret this result as due to the operation of a multitude of *originally* distinct factors, or to the fractionation of some one or more of them. Not very rarely in such series an extreme parental type fails to appear at all (*e.g.* the many-feathered tail of the fantail pigeon [Staples-Brown], or the long glumes of Polish wheat) from crosses with ordinary types. It is difficult to interpret the absence of the extremes simply as an indication of their statistical infrequency. The recent production of an innumerable series of colour forms, as in the sweet pea, is almost [illegible]

colour-complex. Until systematic crossing was undertaken, the extremes existed but the intergrades did not. So also in *Drosophila*, of which the normal eye is red, a profusion of intergrades ranging to the white eye, which was discovered first, has now appeared. Though "mutation" is involved, the essential change is probably the disintegration or fractionation of the originally integral complex.

(5) *Cytological Interpretations of Genetic Phenomena.*—Soon after the rediscovery of Mendelian analysis the plausible suggestion was made that the behaviour of the chromosome in the course of the maturation divisions was consistent with what might be expected if they were actually the bearers of segregable factors. Since, however, the number of segregating factors in many forms far exceeds the number of chromosomes possessed by those forms, it is clear that if the chromosomes are the carriers of factors they must be capable of carrying many. The discovery of linkage, and especially of the fact that linkage was determined by the parental associations of the factors, pointed in the same direction, for, as hinted (by Punnett) in the earlier article on Mendelism (*see* 18.118), linkage or "gametic coupling," as it was then called, might not unreasonably be supposed to be based on chromosomal association. The first development of this conception was made by T. H. Morgan, whose investigations, relating mainly to the fruit-fly *Drosophila*, have inaugurated a new phase in the development of genetical theory. This insect is a subject unusually favourable for experiment inasmuch as it offers a profusion of variations or "mutations," and reproduces itself with great rapidity under laboratory conditions.

The work began with the observation that the eyes, normally red, may be white, and that this variation is sex-linked, behaving genetically precisely as colour-blindness does in man. The white-eyed male mated with normal females produces offspring all normal. Of these the sons cannot transmit the abnormality at all, whereas the daughters mated with normal males transmit the white eye to half their sons. White-eyed females can only be produced as daughters of white-eyed fathers and all the sons of such females are white-eyed. Supposing the male to possess an X-chromosome, this system of descent would be represented if it were assumed that in the normal the X-chromosome carried the dominant factor for red eye (*see* SEX). The linkage with sex is thus found to be an expression of the association of the two determining factors for sex and red eye in the same chromosome.

Numerous other sex-linked characters were soon after discovered, to which the same considerations apply, all collectively composing one linkage-group. The other factors identified in *Drosophila*, amounting to more than a hundred, can all be represented as grouped in three separate linkage-systems which, with the sex-linked group, make *four;* and since from cytological observations the haploid number of chromosomes in this animal is also 4, the inference is drawn that the factors composing each linkage-group are borne in one chromosome. Developing this conception, Morgan suggests that the factors are arranged in the chromosomes as beads on a string, each having a position normally fixed in relation to the rest. Crossing-over is thus represented as the consequence of an exchange of material between homologous pairs of chromosomes in synapsis (*see* CYTOLOGY). The pairs of chromosomes which then conjugate are with much probability regarded as respectively of maternal and paternal origin. The conjugating pairs seem to twist round each other, and occasionally there is (especially in Amphibia) an appearance of anastomosis between them which is regarded as providing for an exchange of material between the homologous pairs, and thus for the formation of cross-overs. According as the linkage between two factors is more or less complete it is supposed that the distance between the position of the two factors in the chromosome is smaller or greater, and in proportion as factors are placed close together the probability of their being separated in the process of twisting and anastomosis is regarded as diminished. The proportion of cross-overs is thus taken as a measure of the position of two factors in the chromosome. If *A*, *B*, and *C* are three factors in one linkage group, and the closeness of the linkages between *A* and *B* and between *B* and *C* respectively be determined experimentally, then from these two the linkage between *A* and *C* can be calculated, and the result of the calculation is commonly found to agree with the value found experimentally for that linkage. In this way the relative "loci" of numerous factors have been determined with fair consistency, and the fact that this can be done forms a strong argument for the belief that in some way at least the factors must be disposed in linear systems. That these systems are actually arranged along the lines of the chromosomes is as yet a matter of inference. Attention must be called to the curious fact that in *Drosophila* crossing-over never occurs in the males in any of the 4 linkage-systems. As in every example of sex-linkage studied, the linkage with the sex-factor is always complete; but all the other factors are liable to crossing-over in the female, though among the male gametes the original parental combinations reappear unchanged. Conversely Tanaka, examining linkages in the silkworm, observed that a pair of linked factors show crossing-over in the male but not in the female, and the two facts together suggest some limitation of crossing-over to the sex which is homozygous in sex, the female in Diptera, the male in Lepidoptera. The development of the idea here outlined has become the subject of very active research and is described in a copious but somewhat esoteric literature which can be followed only with difficulty by those not personally engaged in the work. That the outcome of these researches has led to a valuable codification of genetic principles is not in dispute; but until the main thesis, that the number of independent factors or of linkage-systems is never greater than the haploid number of chromosomes, has been shown to hold generally for animals and plants, this account of the nature of linkage, though probable, cannot be regarded as proved. The defect of the theory at the present time is that it rests on many subordinate hypotheses which are not all capable of independent verification. The position of the factors, for example, is believed to be liable to changes due to the action of other factors, the effects of age and miscellaneous influences difficult to distinguish. Errors of cell-division, long regarded as the most probable source of variation, may also cause disturbance. In two very remarkable instances it has been found possible to connect a disturbance in the normal course of heredity with a visible cytological irregularity—called by Bridges "non-disjunction." In a certain family he observed that a sex-linked character failed to follow its normal distribution to the sexes, and he was able to find that in this family the sex-chromosomes showed corresponding irregularities. More recently (1921) he obtained similar evidence in regard to the fourth chromosome and the group of genes attributed to it. Thus a definite association between particular chromosomes and the transferable factors must certainly exist.

*Giant-forms.*—The interrelation of genetical and cytological phenomena is further illustrated by the behaviour of "Giant-forms." This name is applied to certain varieties (chiefly of plants) in which the haploid and diploid numbers of chromosomes are double those of normal forms. R. P. Gregory bred such varieties of *Primula sinensis*, and found that in respect of various allelomorphs they might be quadripartite and not merely bipartite as the normals are. A plant, for example, might be *DRRR* in colour or leaf-shape, and, in consequence of the extra recessive elements, not distinguishable from the ordinary recessive, though in fact capable of throwing a small proportion of dominants. Since recent cytological studies have shown that series of allied forms may contain various multiples of the lowest haploid number (*Chrysanthemum*, for instance, having 9, 18, 27, 36 or 45), various extensions on these lines may be expected.

*Somatic Segregation.*—In the genetics of plants a number of phenomena have been encountered which are difficult to reconcile with the view, otherwise not unacceptable, that the distribution of the factors occurs exclusively in the maturation processes of the germ-cells. Apart from certain special conditions, best known in variegated plants (which are sometimes irregular mosaics and sometimes consist of an outer "skin" and an inner "core," dissimilar in their genetical potentialities), there are many plants in which the distribution of factors must have been laid down before the formation of germ-cells. E. R. Saunders's results proved that in certain stocks (*Matthiola*) the pollen all carried doubleness though the ovules were mixed in character, single and double. C. Pellew showed that in the hermaphrodite *Campanula carpatica* "*pseliformis*" the pollen bore exclusively femaleness and preponderantly white flower-colour (the plant being heterozygous for blue). The pollen of *Begonia Davisii* (a wild species with single flowers) carries doubleness exclusively, and several similar examples are known, in all of which the segregation of characters must precede the maturation of the germ-cells. Thus, while it is not in question that segregation depends on some cell-division, and very possibly on a differentiation of the chromosomes, there is evidence that the cell-division in which this differentiation occurs must at least sometimes precede germ-formation. As mentioned, in *Oenothera* this "unilateral" distribution is exceptionally frequent.

*Bearing on Evolutionary Theory.*—This aspect of genetics can only be briefly treated here (*see also under* MENDELISM). Genetic analysis has shown that the appearance of variability as a contemporary and widespread phenomenon is largely illusory. On studying a variable species critically it is found that the various forms cannot all produce each other as was formerly assumed, but that they stand in a regular descending order,

being terms in a series of combinations of definite factors. Such series are no evidence of contemporary variability. Many of the terms can be separated in the homozygous condition, and thereafter may breed perfectly true. Even such an appearance of variability as that seen in polymorphic species is frequently not above suspicion of being the consequence of a cross, more or less remote. Contemporary variation certainly may occur, but of the contemporary origination of new species, or of the occurrence of genetic changes which can be colourably interpreted as likely to lead to the production of incipient species in a strict sense, no indication has been found. That the forms of life have been evolved from dissimilar precedent forms we know from the geological record, but as to the process by which this evolution has come to pass we are still in ignorance. All that can be said with any confidence is that variation most commonly arises as an error of cell-division, and that conceivably new species have so arisen.

**GENOA** (*see* 11.597), the chief port of Italy and capital of the province of Genoa. Pop. (Dec. 1918) of the municipal area of about 12 sq. m. (*comune*) 272,221, or, with suburbs (*circondario*), 577,449. The latter figure includes the now contiguous industrial quarter of San Pier d'Arena on the west and a growing residential quarter beyond the Torente Bisagno on the south-east to which the Via Venti Settembre gives direct access. Before the World War there was a marked activity in house-building, but the only buildings of note recently erected are the imposing Banca d'Italia in the Via Dante and the Hotel Miramare above the principal station. The improvement of the Piazza de Ferrari, the central square, was begun in 1913: blocks of houses adjoining the 6th-century church of S. Ambrogio were demolished and the area opened up. The historic Palazzo San Giorgio underwent complete restoration and transformation between 1890 and 1914 and became the headquarters of the Harbour Board (*Consorzio*). A fine new sea-front, the Corso d'Italia, adds considerably to the attractiveness of the new residential quarter.

The birth-rate in 1913 was 20·6 and the death-rate 17·64; 23·25% of the latter were children below the age of five and 11·8% of these died before the age of one year. Mortality was due mainly to pulmonary diseases, heart affections and infantile diarrhœa. The meteorological station (alt. 147 ft.) records the highest mean annual rainfall of the twelve Italian stations of which statistics are available—52 inches. The average number of rain-days is 117. The mean annual temperature is 59·6° F. with a mean of 72·6° in summer and 48·1° in winter and an absolute maximum and minimum of 98·4° and 16·7° respectively. During 1916–8 eighteen earthquake movements were recorded.

The total value of the trade in 1916 was 4,581 million lire, or 39% of that of all Italy. The following table shows the fluctuations of trade in tonnage:

| | Imports. | Exports. | Total. |
|---|---|---|---|
| 1910–1913 (average) | 6,280,000 | 1,230,000 | 7,448,000 |
| 1914 | 5,930,000 | 1,080,000 | 7,010,000 |
| 1915 | 6,560,000 | 900,000 | 7,460,000 |
| 1916 | 6,870,000 | 840,000 | 7,710,000 |
| 1917 | 5,090,000 | 430,000 | 5,520,000 |
| 1918 | 4,530,000 | 300,000 | 4,830,000 |
| 1919 | 5,210,000 | 430,000 | 5,640,000 |

The marked drop in imports which began in 1917 was due mainly to the great decrease in coal—590,000 tons in 1917 as against a previous yearly average of 3,140,000 tons. About 6,600 vessels (exclusive of sailing craft) of an aggregate tonnage of 6,700,000 entered and cleared in 1919, compared with an average of 12,000 vessels of 14,340,000 tonnage during 1911–3. The British share in shipping in 1913 was 1,260 vessels of 2,900,000 tons. The passenger traffic of Genoa (including emigration) had normally amounted to about half a million annually, but it fell to 45,000 in 1916. Emigration decreased from 42,000 in 1914 to 1,500 in 1918.

The port has warehouse and shed capacity for 300,000 tons of general merchandise in addition to coal and cereals. A daily average of 1,000 trucks can be loaded and unloaded. The doubling of the railway track to Pisa and the development of the marshalling station at San Pier d'Arena and of the Genova Brignole station, 3 km. east of the principal station, on the main line to Pisa and Spezia, have aided the improvement of port facilities; also the extension of electric power to the main line towards Turin, and to Savona and beyond on the line along the coast. The power for the latter is supplied by plant of 80,000 H.P. at Cuneo. The new Vittorio Emanuele basin, equipped with up-to-date plant, was nearing completion in 1920 and the construction of the larger basin of San Pier d'Arena had been begun. Shipbuilding (merchant) is increasing in importance; seven steam vessels of 6,900 total tonnage, nine of 7,370 tons and ten of 28,650 tons were built in 1916, 1917 and 1918 respectively.

Woollen factories have been established; the manufacture of felt and straw hats is increasingly important and there is a considerable motor-car industry. The construction of an underground electric railway 6½ m. in length, with 14 stations, connecting San Pier d'Arena with Quarto, 2½ m. east of Genoa, was proceeding in 1920.

**GEODESY** (*see* 11.607 and 8.801).—The term "Figure of the Earth" is sometimes used to denote the form of the sea-level surface or geoid, and sometimes to denote that spheroid of revolution, or three-axial ellipsoid, which most nearly fits the geoid. It is best to confine its use to the latter sense, so that a "determination of the figure of the earth" means the derivation from the results of observation of the lengths of the arcs.

The values obtained by J. F. Hayford in 1909 (1) were:—

| | |
|---|---|
| Equatorial radius of the earth | 6,378,388 ± 18 metres. |
| Reciprocal of flattening | 297·0 ± 0·5 |
| Polar semi-diameter | 6,356,909 metres. |

These figures define a spheroid which certainly fits the northern geoidal hemisphere very closely. Helmert (2), examining Hayford's figures, arrived at somewhat larger probable errors, namely ± 35 metres and ± 0·8, but even so the uncertainty is small.

In the southern hemisphere, however, there have hitherto (1921) been no determinations of importance; and the extension of the African arc, which now stretches from Port Elisabeth to near the northern boundary of Rhodesia, and its ultimate connexion with the Egyptian triangulation are much to be desired.

In 1915 Helmert (3) deduced a value of the flattening from numerous gravity observations and found 1/296·7 ± 0·6. This agrees very closely with Hayford's value and is an important corroboration. The advantage over previous determinations of the figure of the earth enjoyed by his solution lies in the fact that the results of the astronomical observations have been corrected by computing the attraction of all the topography up to a great distance from each station under the assumption of isostatic compensation (*see* below). This procedure undoubtedly frees the astronomical results from a large proportion of the effects of local attraction and so brings the local vertical into much better agreement with the normal to the spheroid than if the correction had not been applied. This solution of Hayford's is in fact so satisfactory that it may almost be said that the problem has been solved.

Geodesy now turns its attention to finding the actual form of the geoid, that is to say, the level or equipotential surface of the earth which corresponds in ocean areas with mean sea-level.

This form will be defined with reference to a spheroid of revolution, and it is not a matter of much importance what spheroid is chosen as the figure of reference so long as it fits the actual geoid reasonably well. Whatever spheroid is selected, careful measurements will reveal the fact that the geoid is slightly irregular with regard to it. The spheroid may be assumed tangential to the geoid at any one point; the two surfaces will not usually be coincident elsewhere. The inclination between the normal to the geoid and the normal to the spheroid is called the deflection of the plumb-line.

The relation of the geoid to the spheroid and the necessity for making the assumption that they are tangential to one another at some arbitrarily chosen point have not always been kept clearly in mind. The idea has been held that the deflection of the plumb-line was everywhere something real and measurable, if the means of measuring it could be found; whereas in reality the spheroid of reference has no existence in nature, and in order to fix this imaginary surface with reference to the real geoidal surface it is necessary to assume that at some particular point the two surfaces touch each other or are parallel. It is not necessary to assume that the origin of the survey is the point at which the surfaces are parallel; we may assume that there is a deflection of the plumb-line there, or not, just as we please. Once the deflection at the origin, the height of the latter above the spheroid, and the axes of this spheroid have been selected, deflections at other points may be derived. If this is done at sufficient points the separation of the geoid from the spheroid can be deduced, and, as the form of the spheroid is known by assumption, that of the geoid also becomes known. The determination of the plumb-line deflections is made by means of a combination of results derived from observations to terrestrial and astronomical objects. If the deflections are found to vary smoothly, so that it appears justifiable to derive intermediate values by interpolation, it becomes possible to integrate the separation of geoid and spheroid due to them, and so arrive at the separation at any point in the area dealt with.

In regions where the deflection is large it is generally also irregular and then interpolation between ordinary triangulation stations may prove inadequate, and it may be necessary to fix additional intermediate stations by triangulation and to make the necessary astronomical observations at these.

An alternative method of measuring the separation of geoid and spheroid may be based on the measurement of vertical angles between triangulation stations, combined with spirit levelling. To do this it is necessary that the plumb-line deflections at the stations shall have been determined. The ray from one station to another is curved in a vertical plane by atmospheric refraction. If this (5) refraction is known it is a simple matter to compute the height of the observed station (whose distance is known) above the horizontal plane through the observing station. It is, however, necessary to find the height with respect to some general datum surface. As the form of the geoid, that is to say the mean sea-level surface, is still unknown, and is in fact one of the objects of the measurement, it is impossible to make a formula applicable to it, and it is necessary to have recourse to some assumed reference figure, and the obvious figure is the spheroid which has already been used in connexion with the deflections of the plumb-line. The vertical angles corrected for refraction can be reduced to the spheroidal vertical by applying the component of the plumb-line deflection, and then it is quite straightforward to compute the height of the observed point above the spheroid. By means of spirit levelling it is possible to find the geoidal height of the station observed, for spirit levelling with its short rays intimately follows the geoidal level surface. Both spheroidal and geoidal heights of the observed points are thus obtained and the difference between them is the separation of geoid and spheroid.

It has not generally been pointed out that the triangulated heights and spirit-levelled heights are not strictly the same thing. Triangulated heights have very rarely been properly reduced, taking account of plumb-line deflections and refraction, and so have not meant anything very precise, but they are certainly not geoidal heights. Geoidal heights have many practical uses and are what would generally be required by engineers, but from the geodesist's point of view they do not mean much until the form of the geoid, to which they refer, has been determined.

*Isostasy.*—The theory of isostasy postulates that the apparent excesses of matter in the earth's crust, consisting of continents and mountains, and the apparent deficiencies, corresponding to oceans, are compensated by underlying variations of density, mountains being compensated by a low density and oceans by a high density in the material below them. These variations of density constitute the isostatic compensation of the topographical features.

In 1909 Mr. Hayford of the U.S. Coast and Geodetic Survey published his work on the figure of the earth and isostasy (8); he suggested the idea of isostatic compensation being complete at a depth small in comparison with the earth's radius; that is to say, he supposed that all those arrangements of crustal density required to make good the deficiency of height in a column under the sea, or to balance the excess of height in one under a mountain, would be found in a crust of moderate thickness, and that all matter at a greater depth was either homogeneous or arranged in homogeneous layers. He also assumed, partly from considerations of convenience, that the excess or defect of matter was distributed uniformly from sea level to that depth, which he named the "depth of compensation." Computing the attraction of the visible topographical features upon those stations of the U.S. Triangulation at which the deflection of the plumb-line had been determined, and trying the effect of isostatic compensation complete at various depths, he arrived at the conclusion that the most probable depth of compensation is 122 kilometres. Using this depth and calculating the deflections that the visible topography and its compensation would produce, he finds that the average residual, that is the difference between the observed and the calculated deflection, is only one-tenth of what it was before the correction for compensation was applied. From this he concludes that in the U.S.A. the existence of a close approximation to isostatic equilibrium is proved, and that this equilibrium is complete at a depth which does not differ very greatly from 122 kilometres.

Hayford's hypothesis was subsequently applied to the pendulum stations of the U.S. C. and G.S. (9) and the results obtained were in good accord with those deduced from the deflections of the plumb-line. The hypothesis was also applied to the deflections and pendulum observations in India but the results did not appear to be so favourable. In a further discussion of the American results Mr. W. Bowie (10) endeavours to trace a connexion between the gravity residuals and the geology of the regions surrounding the stations, and has a certain measure of success. He points out, however, that if there is, for instance, a surface sheet of dense rock of wide extent, compensated by lightness in the deeper crust, the pendulum will not be able to reveal the fact, for the attraction of an extensive disc on a point above its centre is independent of the height of the point so long as the height is small in comparison with the radius of the disc, so that the effect of the excess of matter in the dense sheet of rock immediately under the station will be *exactly* counterbalanced by the negative effect of the corresponding deficient density in the lower strata of the crust. If the dense sheet were of small extent the pendulum would reveal its presence, for its closeness to the pendulum would make its effect more potent than that of the more deeply situated deficiency which compensates it, and gravity would therefore be greater than if the whole were homogeneous. Sir Sidney Burrard (11) applies the idea of allowing for geological peculiarities to India, where the Gangetic plain is an example of an area covered by alluvium of low density which probably extends downward to a considerable depth. He also shows that the distribution of crustal density required to account for the low values of gravity found at stations of the Gangetic plain will go some way, at least, towards explaining the high values of gravity found at stations along the margin of the alluvium. The

excess of density required in the deeper parts of the crust, to make good the lightness of the alluvium, will from its position exert a positive attraction on a pendulum off the alluvium on either side, more than sufficient to counteract the negative effect of the lightness of the alluvium itself, for the latter will be nearly in the same horizontal plane as the pendulum and therefore unable to produce any appreciable downward pull, so that there will remain a somewhat greater attraction on stations off the alluvium than if the whole had been homogeneous. These considerations tend to remove the discrepancies between the results of observation and those of calculation in the Gangetic and Sub-Himalayan region and Sir Sidney Burrard concludes that the Gangetic trough is isostatically compensated.

The depth of compensation is not a quantity which should be regarded as definitely determined. Mr. Bowie finds a good deal of evidence for a smaller depth of about 96 kilometres. In average country the effect on the computed deflections, or values of gravity, of changes in the assumed depth are so small that the evaluation of the depth cannot be very precise.

*Base-Line Measurements.*—The system introduced by E. Jäderin o Stockholm, of measuring with stretched wires, may be said to have superseded the older methods and it is improbable that any kind of bar will again be used for this purpose. It is now recognized, moreover, that nothing is gained by measuring a short base with extreme accuracy as this accuracy is lost in the process of connecting the base with a side of the primary triangulation. The best course is to measure a side of the primary triangulation itself, but it is not often that this can be done, though the use of stretched wires instead of bars makes it possible to carry base measurements over much more uneven ground than of old. Jäderin's original plan was to use two wires having different coefficients of expansion and from the difference between their lengths, as disclosed in the process of measuring, to deduce their temperature. In the United States, where tapes are generally used, uncertainty as to the temperature was much reduced by the expedient of making the measurements by night. The discovery of "Invar" by C. E. Guillaume almost entirely removed the need for these special precautions. A wire of the thickness generally used, namely 1·65 mm., is not much heated by the rays of the sun and the error made in assuming that its temperature is the same as that of the air is not large. The average coefficient of expansion of invar is about $4\times10^{-7}$ per 1° C., so that an error of 2½° C. in the adopted temperature of the wire would produce an error in the measurement of only 1/1,000,000. The methods of making measurements with invar wires have been closely studied by Benoit and Guillaume (12) and their procedure may be confidently followed.

For the standardization of the wires at the observatory, before and after the measurement of the base, different methods of laying out a length of 24 metres, which is the usual length of the wires, have been employed. An apparatus designed by Sir David Gill for the trigonometrical survey of India is fully described in *Engineering* 1915.

The ultimate standard of length which was supplied with this apparatus is a nickel bar of H section one metre long. Standards for ordinary use are H bars of invar one metre and four metres in length. Invar has been observed to undergo a secular change in length which continues for many years. This constituted a serious drawback, but according to a recent investigation by Guillaume the instability is due to the presence of carbon which gradually forms cementite, $Fe_3C$, with the iron. The addition of chromium, which has a greater affinity for carbon than iron has, prevents this, and an invar with tenfold increased stability has been produced.

*Triangulation.*—For measuring horizontal angles the use of theodolites with horizontal circles of more than 12 in. diameter is now unusual. For primary triangulation the use of opaque signals has now been almost entirely abandoned. Luminous signals, *i.e.* heliotropes by day and lamps by night, are universally employed and there is a tendency to regard the night as the best time for observing horizontal angles, though for vertical angles it is necessary to choose the time at which refraction is most steady, namely from about 1 to 3 P.M.: at this time of day refraction is also a minimum.

In countries where continuous sunshine is rare the night is no doubt preferable to the day, but where sunshine can be counted on the best results for horizontal angles, that is to say those least influenced by lateral refraction, are probably to be obtained from a combination of day and night measures.

*Control of Triangulation.*—As triangulation extends from its initial base errors are generated and controls are required to prevent these errors from accumulating unduly. These are provided by the measurement of additional bases and by introducing Laplace points at suitable intervals along the triangulation. At Laplace point, where the azimuth is observed astronomically, and the longitude determined by telegraph, a check is introduced on the triangulated azimuth precisely similar to that given by an extra base on the triangulated length of the side. The question to be decided is the proper interval at which bases and Laplace points should be introduced. When the error in length of side generated in the triangulation is probably two or three times as great as that of a base it will be desirable to introduce a check base. The formulae of de Graaff Hunter (14) give the means of calculating the probable error accumulated in the triangulation.

In the first place a quantity $M=(1+f)m\sqrt{\frac{18}{\Sigma}}$ for each series of the triangulation under discussion is to be computed. This quantity measures the precision of the series and enters into the determination of the probable error. In it $m=\sqrt{\Sigma\Delta^2/n}$ is Ferrero's error of mean square of a single observed angle, $f$ is a factor ranging from 0 to 1/6 depending on the type of figures of which the series consists, and $l$ is the average length of side in miles.

Then P.E. in seconds of azimuth of terminal side of a series $=1''\cdot575\sqrt{\Sigma M^2S}$

P.E. in 7th place of log. of terminal side of a series $=33\cdot2\sqrt{\Sigma M^2S}$

in which S is the length of the series in units of 100 miles. The summation is for different series for which values of M differ. If one straight series only is considered the above quantities become

$$1''\cdot575M\sqrt{L}$$

$$33\cdot2M\sqrt{L}$$

where L is the length of the series in units of 100 miles. It may be pointed out that there is no symbolic difference between azimuth error expressed in radians and error in Napierian log. side, and with these units the same description applies to one or other.

If we take $\frac{1}{10}$ as the probable error of a measured base it will be desirable to introduce a check base as soon as the probable error of the length of a side of the triangulation amounts to three times this quantity; this stage is reached when

$$33\cdot2M\sqrt{L}=3\times10^7\times\log.(1+10^{-6}).$$

In first-rate triangulation the value of M will be about 0·2, using this value L = 384 m.

If $\Delta A$ = astronomic-geodetic azimuth, Laplace's equation becomes

$$\Delta A.\operatorname{cosec}\lambda_2-\Delta A\operatorname{cosec}\lambda=(L-L_2)-15T$$

where $(L-L_2)$ is the computed longitude difference and T is the difference between the local times at the two ends of the triangulation.

This equation serves to determine $\Delta A$ whence the true geodetic azimuth follows. The P.E. of an azimuth observation, $\delta A$, may be estimated at about 0″·2 in high-class work, that of T at about 0ˢ·03, or $\delta L=0''\cdot45$, hence in latitude 45° the P.E. in azimuth determined from a Laplace equation is $\sqrt{(\delta A^2_0+\delta A^2+\delta L^2\cdot\sin^2\lambda)}=0''\cdot4$, which in radians is roughly $2\times10^{-6}$. This is twice as large as the value which was adopted as the P.E. of a base and shows that the precision of azimuth and longitude observations must be increased if they are to be brought up to the standard already reached in base-line measurements; that is to say, it indicates that in the case of triangulation in which M is as small as 0·2 it would not be justifiable to attempt to control the azimuths by means of frequent Laplace points unless the observations at the latter can be improved.

*Determinations of Height.*—The precision of spirit levelling is so great as to justify the recognition of the lack of parallelism of the various level surfaces, each of which is approximately spheroidal. It is nowadays customary in levelling of high precision to apply to the observed differences of height the correction (15) (16) for the convergence of these surfaces, that is to say the orthometric correction, and to publish the orthometric heights.

As regards differences of height found by triangulation much improvement is called for. Refraction has always been a source of great uncertainty, and it has perhaps been looked on as more intractable than it really is. Further research is required. Few field observations provide suitable material for investigating the question, owing to lack of information as regards (*a*) plumb-line deflection, without which it is impossible to reduce the observations to the reference spheroid, and (*b*) rate of change of the density of the air with height, on which the refraction depends. A consideration (§) of the ordinary physical laws leads to a formula which represents very well the refraction usually met with, when these are not burdened with error due to neglect of plumb-line deflection.

Observed vertical angles are referred to the local geoidal vertical; when reciprocal observations have been made at two points $A_1$ and $A_2$, if $E_1$, $\omega_1$, $\delta_1$ are respectively the angle of elevation, the refraction and the deflection at $A_1$ towards $A_2$ and with changed suffixes for $A_2$, then

$$E_1+\delta_1-\omega_1+E_2+\delta_2-\omega_2+c=0$$

where c is the angle between the verticals at $A_1$ and $A_2$. It has been customary to neglect $\delta_1$ and $\delta_2$ and to assume $\omega_1=\omega_2=0$, whence the equation becomes

$$\mathfrak{E}=E_1+E_2+c=0.$$

As $\delta_1+\delta_2$ may easily exceed the error of observation and as $\omega_1$ and $\omega_2$ are appreciably different, values of refraction so deduced are of little value. There is no reason why this state should continue. Properly reduced vertical angles will give good values of heights above the selected spheroid and the differences of these heights from the heights obtained by spirit levelling will reveal the separation of the geoid from this spheroid.

*Astronomical Latitudes.*—For the observation of latitude the Zenith telescope and the Talcott-Horrebow method seemed to have superseded all others (see 11.610), but the prismatic astrolabe and the method of equal altitudes have advantages for special purposes which entitle them to consideration. This instrument, which was invented by MM. Claude & Driencourt (17), determines the time and the latitude simultaneously, thus doing the work of the Zenith telescope and the transit instrument at the same time. Those who have used the astrolabe claim that a set of observations (18), which can be made with an instrument of small size in two hours, suffices to determine the time within one-tenth of a second, and the latitude within one second of arc. It is probable, however, that the time observation is liable to be considerably affected by the personal equation of the observer.

The principle of the prismatic astrolabe is that of equal altitudes. The axis of the telescope is horizontal. In front of the object glass an equilateral prism is mounted with its edges horizontal and the face next the object glass vertical; below, and slightly in front of the prism, there is a bath of mercury. The rays of light from a star at altitude 60° strike the upper face of the prism perpendicularly and are reflected from the opposite face into the telescope; the rays which fall on the mercury are reflected upwards, strike the lower face of the prism at right angles, are then reflected from the opposite face and enter the telescope parallel to the rays which reached the prism direct; thus two images of the star are formed in the telescope which approach each other as the star approaches the altitude of 60° and then separate again. The observation consists of noting the time at which the images pass each other. Each observation of this kind gives a locus, analogous to a "Sumner" line in navigation, on which the zenith of the station of observation must lie. Three such observations to suitably situated stars should, if everything were perfect, result in three concurrent lines, but will in general produce three lines forming a triangle and care must be used in deciding on the true position of the zenith, which will not necessarily be inside the triangle. If four stars are observed the case is clearer and it is advisable therefore to observe four stars as a minimum; of these one should be in each quadrant of the heavens; that is to say, one to the N.E., one to the S.E., one to the S.W., and one to the N.W. of the station at the moment of crossing the circle of 60° altitude. When the observations have been made the chronometer error and the latitude of the place can be deduced from them by means of a simple graphical construction which gives results as accurate as the precision of the observations allows. If certain preliminary computations have been performed beforehand the graphical method can be carried out very quickly and the results obtained in a few minutes after the completion of the observation.

*Longitudes.*—The development of wireless telegraphy (*see* SURVEYING) has removed the chief difficulty of determining the longitude and there is now no reason why astronomical longitudes should not be used as freely as astronomical latitudes.

The time signals emitted by the Eiffel tower in Paris are of an accuracy superior to that of any ordinary determination of local time, and they have been picked up without much difficulty (1921) by means of a portable apparatus at a place as far from Paris as Dehra Dun, India, to which the distance along a great circle is about 60°. The "Scientific time signals" are sent out from Paris at 23·00 C.M.T. (civil). After certain warning signals, 300 dots are sent at equal intervals, the whole occupying about 293 seconds. These are heard in a telephone in which the clock-beats are also produced. It is also necessary to note the time at which there is a coincidence between a dot and a clock-beat. The precise time of the first and last of the 300 dots is also signalled and a simple computation connects the clock with G.M.T. With good hearing conditions there seems little room for personal equation in this part of the observation. In the determination of the local time there is less certainty; unexplained differences of 0·1 and even 0·2 occur.

Thus in the Paris–Washington arc, 1913–4, the values obtained by the interchange of the American observers were:—

$$5\text{-}17\text{-}36\cdot549 = \cdot0051 \text{ and } 5\text{-}17\text{-}36\cdot758 = \cdot0027$$

(h m s)

A similar difference was obtained when the French observers were exchanged. Two separate determinations of the Greenwich–Paris

(m s) (m s)

are gave 9·20·977 and 9·20·910. These differences have been the subject of discussion (29), and are receiving a good deal of attention; it is to be hoped that the source of error will be discovered and that longitudes correct to 0·01 sec. will be obtained.

Longitude determinations are required in order to provide Laplace points for the control of the triangulation and also for the investigation of the deflection of the plumb-line. The use of wireless telegraphy will greatly facilitate the former because in the past it has often been difficult to find a place where it was possible to get a connexion with the telegraph wires and also to make satisfactory azimuth observations. By the multiplication of longitude stations knowledge of the deflection of the plumb-line in the prime vertical will be much improved, especially in low latitudes where the effect of such a deflection on the azimuth is so small that the comparison of observed and computed azimuths is incapable of giving trustworthy results.

*Gravity.*—A very important addition to the half-seconds pendulum apparatus designed by Col. R. von Sterneck (*see* 8.809) of the Austrian survey is the means of measuring and correcting for the movement set up in the stand by the swinging pendulum. This movement is named by German observers "das Mitschwingen"; in the Coast and Geodetic Survey of the United States it is called "the flexure." Probably the best English word to describe it is "the sway."

Two methods of measuring it are in use. The C. and G.S. measure the actual to-and-fro movement of the top of the stand by means of an interferometer (20). The effects of different amounts of movement on the pendulum's time of oscillation are found by experiment and an empirical formula is used for reducing this time to what it would have been if the stand had been perfectly rigid. The movement is expressed as a fraction of the width of one of the bands or fringes in the interference grating. Using monochromatic sodium light it was found that a movement of 0·1 fringe corresponded to a correction of $17^{s}\cdot8\times10^{-7}$ in the time of vibration of the half-seconds pendulum. A movement of 0·1 fringe means a linear displacement of the pendulum support of 0·029μ.

The other method introduced by Prof. Schumann (208) of the Prussian Geodetic Institute is as follows: Two pendulums of equal period are suspended on the stand, with their knife-edges parallel to each other and in the same horizontal plane. Of these one is set swinging, the other being at rest, and the rate at which the latter acquires an oscillation, from the swaying of the stand induced by the swinging of the former, is a measure of the rigidity of the stand and affords the means of computing a correction to the time of oscillation. With this method the probable error of the correction derived from four observations, two taken before and two after a series of pendulum swings, is about $0^{s}\cdot5\times10^{-7}$. The amount of the correction where circumstances are favourable may be expected to be about $40^{s}\times10^{-7}$.

The absence of means of determining the correction for sway was perhaps the principal source of uncertainty in the results of the older series of pendulum observations and the methods which have been described formed an important advance.

Numerous observations with pendulums for the determination of the force of gravity have been made of recent years in various parts of the world and the effect of applying the theory of isostasy to the computation of the normal value has been extensively tried in America and in India. By normal value is here meant that value which is arrived at by the use of the formula which gives the force of gravity at sea-level in any latitude and the application to that value of the correction for the height of the station above sea-level, and for the attraction of the topography of the whole earth with its isostatic compensation.

The formula deduced by Helmert from the discussion of a large number of observations in different parts of the world was

$$\gamma_0 = 978\cdot030\ (1 + 0\cdot005302\sin^2\phi - 0\cdot000007\sin^2 2\phi)$$

(*see* 8.801).

For the area of the United States it was found that an equatorial value of 978·039 (9) agreed better with the observed results, and in India the value of 978·041 (21) was found the best.

In 1915 Helmert (3) deduced a formula from the 3,000 stations which had been reduced to the Potsdam system by Borrass in 1912, in which he supposes the equator to be an ellipse so that the longitude L as well as the latitude $\phi$ has to be taken into account. The formula is:—

$$\gamma = 978\cdot052 \left\{ \begin{array}{ll} (1 + 0\cdot005285\sin^2\phi - 0\cdot000007\sin^2 2\phi & \\ \quad +7 \qquad +0\cdot000018\cos^2\phi\ \cos 2(L+17^\circ)) & \\ \quad +4 \qquad\qquad\qquad\qquad +6 & \end{array} \right\}$$

This formula is applicable to continental stations situated at least 100 km. from the edge of the continental shelf, that is from the 110-fathom (200-metre) line.

It is assumed that the semi-axes of the equatorial ellipse differ by 230 metres and that the major axis lies in 17° W. longitude. Clarke (4) in 1878 deduced an elliptical equator in which the semi-axes differed by 465 metres, the major axis lying in 8°15′ W. longitude.

The advantage of using an elliptical equator seems rather questionable; it would appear preferable to regard inequalities of the equatorial radius as deviations of the geoid from the spheroid of reference rather than as fulfilments of a mathematical law, but it is of interest to know that the geoid presents such an irregularity.

For measuring the force of gravity at sea various kinds of apparatus have been tried. The underlying idea is to balance the weight of a column of mercury against a pressure, which is either constant or measurable, and which is independent of gravity.

Hecker used the pressure of the atmosphere as in an ordinary barometer and measured it by means of boiling-point thermometers. Duffield has tried an aneroid in place of the boiling-point thermometer and more lately has balanced the mercury against a constant mass of air, the whole apparatus being closed. The success so far attained is not very great but the last-mentioned device seems capable of improvement and may prove a satisfactory instrument.

The variation of gravity on land has been studied by Baron Roland Eötvös (23) (24) (25) with an instrument of quite a different kind, namely, the Gravity Torsion Balance. This instrument does not measure the force of gravity but the rate of change in the force of gravity at any point and the direction in which that rate is greatest.

The force of gravity $\gamma$ in latitude $\phi$, is given by the formula $\gamma = 978\cdot00(1 + 0\cdot00531\ \sin^2\phi)$ C.G.S., hence the change in $\gamma$ corresponding to a change of 1″ in latitude in latitude 45° is $25\cdot2\times10^{-6}$.

and the length of 1° of meridian in latitude 45 being about 3,108 cm. the change in 1 cm. is $8.1 \times 10^{-9}$. Along the parallel there is no change. These are the normal values. The Torsion balance determines the actual rates of change at the point of observation and the direction in which this rate is a maximum. Eötvös calls this maximum rate the "Gravity Gradient," Gr(g). The instrument consists of a light horizontal tubular beam 40 cm. long suspended from its centre by a fine platinum wire about 50 cm. long; at each end of the beam there is a weight of 28 gr., the one inserted in the tube and the other hanging from it by a thread about 60 cm. long. The whole is enclosed in a case so constructed as to protect the interior as far as possible from inequalities of temperature. The case is capable of being rotated on a vertical axis into different azimuths, and it is by measuring in each of a series of positions the amount of torsion of the suspending wire that is required to balance the small forces acting on the beam and tending to cause it to take up a position coinciding with the direction of Gr(g), that the direction and magnitude of Gr(g) are determined.

The quantities which the Eötvös balance is capable of measuring are almost incredibly small, $1 \times 10^{-9}$ C.G.S. being rather larger than the average of the differences which it is able to detect. The data furnished by this instrument afford the means of tracing the form of the geoid and, after the effects of the visible topography have been allowed for, of detecting the presence of subterranean irregularities of density. A large number of observations with this instrument have been made in Germany since 1917 under the direction of the Prussian Geodetic Institute, chiefly with the object of studying its applicability to geological research; that is to say, for the location of masses of abnormal density.

**GEOGRAPHY** (*see* 11.619).—The application of geography to matters connected with the World War and the peace settlements took two main directions. The first was concerned with all those special naval and military studies and operations of which the results are expressed principally on maps (*see* MAP). The other showed geography in what may be termed its encyclopaedic aspect, in which, to a prefatory description of a territory in its topographical and (so far as appropriate) its geological, botanical, and other scientific aspects, there must be appended a discussion of its social, political, and economic conditions, its communications, history, and so forth: in short, an account of the activities of its inhabitants in whatever direction. For example, much work of this general character was executed by British intelligence organizations such as the geographical section of the Naval Intelligence Department and the historical section of the Foreign Office, the French *Service Géographique de l'Armée*, and others. Most of this work was carried out by organizations created *ad hoc;* much of it was of permanent value apart from its immediate military and political uses; and, generally speaking, it indicated many desirable directions for geographical research and the collection of data, which might have been placed on a permanent footing but for restrictions imposed by financial considerations after the war.

Expressed in the broadest terms, the keynote of geographical study on this side is the relation of man to his geographical environment. A natural corollary is to view the world first in natural regions, as defined by physical conditions of climate, relief, vegetation, etc.; afterwards to correlate ethnographic, linguistic and political divisions with these. The study and definition of natural regions, at any rate on broad lines, is specially associated in Britain with the name of Andrew John Herbertson, professor of geography in Oxford University. This division of the earth into natural regions, and the influence of the conditions of each upon its inhabitants, is obviously capable of application not only on broad simple lines to the world generally, but locally and minutely in special areas. In this last direction there is an almost infinite field for research: it is necessary at all times that its practical application should be kept in view, and trivialities, on the one hand, and too bold generalizations, on the other, avoided.

This relationship between man and his environment as prescribed by natural regions has thus become a leading motive of geography, in research and as an educational subject, in Britain and in Europe, especially among French and German geographers, and elsewhere through the local and individual work of such investigators as Prof. J. Cvijić in the Balkan area. In the United States, too, this view of geography has taken firm hold, though here it did so later, as at first the modern development of geographical study tended rather towards the physiographical side (land forms) alone. In the wider field such workers as Ellen C. Semple, Prof. R. de C. Ward, W. L. G. Joerg, Prof. I. Bowman, and others, turned their attention to many parts of the world, but especially, perhaps, to their own country, and a proposal was made to the Association of American Geographers that, by way of a basis, a map dividing the United States into physiographical provinces should be prepared with the collaboration of all American geographers and institutions interested.

Distributional surveys, whether physical or ethnographical or economic, or of whatever sort, are in fact the chief requirement of this branch of geography, though the prospect of their being put in hand on international or even national lines is remote. In certain special directions international action has been taken, as for example the expression of the need, and the laying down of certain general principles, for a series of international aeronautical maps, which was voiced in the convention for aerial navigation signed by about 30 States in Paris in Oct. 1919. But a proposal for an International Geographical Union, which arose out of the formation of the International Research Council in 1918 by national academies of the principal Allied Powers, was not welcomed with unanimity, although one was formed for geodesy and geophysics. It was not only as regards geography among the sciences, however, that doubt was expressed as to the present possibility of working international unions, in view of the preoccupation of workers with the reorganization of their individual work at home. Such work is largely concerned with the establishment of geography as an educational subject (see below). As a special example apart from this, mention may be made of the work undertaken in 1919 and following years by a permanent British committee representing the Admiralty, the War, Foreign, Colonial, India, and Post Offices, the Boards of Trade and Agriculture, and the Royal Geographical Society, which was charged with the preparation of lists of standard spellings of geographical names, the divergent

systems or lack of system characteristic of maps and geographical works hitherto having been found to be a real inconvenience in geographical investigations during the war.

*Education.*—The position of geography in the British educational system came periodically under discussion before the war, and had been materially strengthened in some directions, but not in all. The war, for obvious reasons, broadened interest in this subject, and its consideration was actively resumed in and after 1917. Broadly speaking, it may be stated that the position of geography was consolidated as an elementary educational subject, and that its appeal was widened as a university subject, as evidenced by the establishment of honours courses in geography and the endowment of professorships (*e.g.* Cambridge University geographical tripos, 1919; chair of geography and anthropology, University College, Aberystwyth, 1918). Geography had become widely studied as a subject for the school certificate examination, although complete agreement had not been reached as to its exact scope for this purpose: for example, while one syllabus began with the study of the distribution of land and water, another went farther back, to demand some knowledge of the position of the earth as a planet, and its movements. The subject is recognized as valuable, not only for its own sake as teaching something about the world, but as a pointer to special directions of study, such as geodesy, surveying and military topography, and as an essential adjunct to such subjects as history and economics, and certain aspects of biology. It was in regard to these special applications, and particularly so far as they are appropriate to advanced courses in schools, that the position of geography in education remained weak: a subject so elastic in comparison with other school subjects must necessarily be difficult to define by means of a syllabus, and it did not find wholly satisfactory expression in advanced text-books. Regarding geography thus, as a species of pivot for the study of other subjects, we may be in danger of assuming that so long as these other subjects are viewed and taught with a proper conception of the place of geography in them, the teaching of geography itself is of no consequence. But the geographical view and teaching can hardly be ensured if they be left dependent upon teachers and students of kindred branches of learning, as indeed has been sufficiently demonstrated by the position of geography in education down to quite recent years.

*Exploration.*—Even though virgin areas of the earth's surface be now few, explorers have still many fields in which to labour at the filling-in of details. Meanwhile in the Arctic and Antarctic regions, especially the latter, there are still large areas unknown, despite the work of important expeditions (*see* POLAR REGIONS). In Africa plenty of geographical knowledge remains to be acquired. Here and in the tropical islands of the Malay Archipelago, especially New Guinea, where at many points development by white men is only in an early stage, exploration may be regarded as almost within the routine duties of European administrators, and is more or less constantly in progress.

The other principal fields for exploration are Canada and Alaska, and certain parts of South America and Asia. As regards Canada and Alaska, in addition to the investigation of the Arctic coast lands, reference may be made to Mr. Howard Palmer's study (1910) of the orography of Mt. Sir Sandford and its vicinity in the Selkirk range, B.C., to Dr. J. Norman Collie who was travelling north of the Yellowhead Pass in 1911, and to other investigators who extended the detailed knowledge of the Canadian Rockies in various directions. The research committee of the National Geographic Society granted $5,000 for the continuation in 1911 of the glacial investigations in Alaska by Prof. R. S. Tarr and Prof. L. Martin, who led the Alaskan expedition of the Society in 1909–10 in the region of Yakut Bay, Prince William Sound, and the lower course of the Copper river. The demarcation of the Alaska–Canada boundary, running for 600 m. along the meridian 141° W., occupied commissions under Messrs. T. D. Craig (Canada) and T. Riggs (United States) from 1907 to 1914, when about 200 permanent boundary marks were erected. In connexion with exploration reference may be conveniently made to the investigation of natural resources, on which subject the Canadian Commission of Conservation has issued a valuable series of reports (down to 1920), dealing with water-power in British Columbia, power (including water, coal and natural gas) in Alberta, etc.

In South America, Major Fawcett in 1910 undertook further exploration in Bolivia, in the valley of the Heath and adjacent territories. Following upon earlier reports by this officer, work on the demarcation of the Brazil–Bolivia boundary was proceeded with in 1911–2. In Jan. 1911 Col. A. J. Woodroffe led a party of British officers lent to the Peruvian Government for the demarcation of the frontier with Bolivia, and the work was carried on in 1912–3. The Yale Corporation sent an expedition to Peru in 1911, under the direction of Prof. Hiram Bingham, with Prof. Isaiah Bowman as geographer and geologist, and Mr. K. Hendrikson as topographer. It was divided into three parties, to carry out archaeological, topographical, and geological explorations, and had three fields of operations—the Urubamba river and its affluents, a trans-Andean section from the head of navigation on the Urubamba to the Pacific, and the vicinity of Mt. Coropuna (the estimated height of which was reduced to 21,700 ft.) and Lake Parinacochas. Notes on the human and economic geography of the region were collected by Bowman, who followed up this work by making another journey in 1913, when he made similar studies in the Andes of north-west Argentina, the Titicaca-Poopo basin, and the desert of Atacama. Prof. W. Sievers in 1909–10 placed the true source of the Marañon (upper Amazon) in the glacier of Mt. San Lorenzo. In 1912–3 Dr. Hamilton Rice was at work in the north-west of the Amazon basin, S.E. of Bogotá, Colombia, and in the same years Dr. Koch-Grünberg made a second expedition in northern Brazil, about the headwaters of the Branco and the Orinoco and the connecting waterway of the Cassiquiare.

Among recent journeys in central Asia may be mentioned that of Mr. D. Carruthers, whose party, in 19 months' work (1910–1), covered much ground in the upper Yenisei region, Mongolia and Dzungaria. In the same years the French traveller Dr. Legendre carried out important exploration in western China, especially in the valley of the Yalung between 28° and 30° N. In India, Sir M. A. Stein investigated (1911–2) numerous sites of archaeological interest in the course of an exploratory journey on the north-west frontier, and in 1913–5 extended his researches in the Lop-nor, Turfan, and other areas, including the Pamirs. The punitive expedition (1912) against the Abors in the north-east added considerably to topographical knowledge in spite of extreme difficulties of transport, heavy forests, and misty and wet weather. One party explored the River Dihong as far as Shimong for the first time, and carried mapping above that point; another surveyed the Padam Abor country; others, again, broke new ground in the Galong Abor country and in the valley of the Subansiri. Considerable corrections were found necessary in existing maps. In 1913 the Indian and Russian triangulations were connected, after an arduous piece of survey through the difficult country from Gilgit up the Hunza gorge and over the Kilik pass. Maj. P. M. Sykes continued his journeys in Persia, and in particular studied the problems connected with the ancient territory of Parthia. Dr. A. Musil in 1910 made further explorations in northern Arabia, in the region adjacent to the Hejaz railway. He claimed to have accurately identified for the first time the Mount Sinai of the Bible. The extensive surveys carried out in Mesopotamia during the war may fairly be mentioned in connexion with exploration; the information previously available, both cartographical and verbal, concerning this country was found on critical examination to be unreliable in many directions. The surveys executed in 1914–8 covered nearly all southern Mesopotamia, with adjacent parts of Persia and Arabia.

In 1920–1 an expedition having for its objects the ascent of Mt. Everest, and (as ancillary thereto) the scientific study of the territory surrounding the mountain, was organized by the Royal Geographical Society and the Alpine Club. The consent of the Dalai Lama of Tibet was secured, and arrangements

were made to despatch a reconnaissance expedition during the summer of 1921 so as to determine the best direction for attempting the ascent, which should be undertaken in 1922. Col. C. Howard Bury was appointed chief of the expedition, and Mr. H. Raeburn as leader of the reconnaissance. (O. J. R. H.)

**GEOLOGY.**—Progress in scientific geology during 1910–21 is here discussed in four sections: (1) cosmic, (2) dynamical, (3) structural and (4) stratigraphical.

## I. Cosmic Geology

Cosmic geology (*see* 11.648) deals with three main groups of problems: (1) the early history of the earth as inferred from its composition and structure, and from analogy to other heavenly bodies; (2) the physical conditions which by their influence on climate have controlled the origin and evolution of life on the earth; (3) the plan of the earth or distribution of continents and oceans as determined by the upheaval and sinking of the surface and by the formation of the valley systems due to dislocations of the crust (*see* Plate). On all these questions scientific opinion had become more definitely crystallized by 1921, through the further discussions during the previous decade.

*The Origin of the Earth.*—The origin of the earth may be learned either from study of its composition and structure or from cosmogony and its analogy to the stars. Only a small proportion of the earth's materials are available for direct observation, but indirect methods have demonstrated three facts about the inaccessible interior. It is hot, heavy, and consists of zones having very different physical properties. That the interior of the earth has a high temperature is shown by hot springs, by the warmth of deep mines, by the molten condition of the lavas that are raised to the surface through volcanoes, and by the evidence that all deep-seated rocks have been either melted or re-crystallized under great heat. The temperature below the surface rises at a rate which is known as the geothermic gradient. The average rise has been often estimated as about 1° F. for every 53 ft. of descent. The high temperature of some Queensland hot springs would, unless their water came from a much greater depth than the layers reached by the wells, indicate a gradient more than twice as fast. On the Rand goldfield, on the other hand, the rate may be five times as slow, for at the Village Deep mine it is only 1° F. for every 253·9 ft. of descent. The rate of increase is naturally quickest near active volcanoes, and it varies in accordance with the geological history of an area and the composition and thermal conductivity of the rocks. The famous observations at the Rose Bridge colliery at Wigan showed that the geothermic gradient varied from 1° F. for 33 ft. to 57·7 ft.; in the upper part the rate was 1° F. for every 57·7 ft., in the lowest part the average was 1° for 48·2 ft. A persistent increase of 1° F. for 50 ft. would amount to approximately 100° per m.; so the temperature would be at 2,000° F. at the depth of 20 m., and at 100 m. deep would be of solar intensity. It is, however, probable that the material of the deeper parts of the earth is a better conductor of heat than the rocks of the crust; so the geothermic gradient may become more gradual in depth and below perhaps 40 m. the temperature may be almost uniform, and 2,000° F. may be the highest temperature within the earth.

The second certain fact about the inner earth is that its material is much heavier than the rocks of the crust. The average specific gravity of the crust is about 2·5, whereas that of the earth as a whole is about 5·7. The heaviness of the internal material may be due either to its condensation by pressure or to its composition largely of heavy metals. That the latter explanation is correct is indicated by the evidence of meteorites, of radioactivity, and of earthquakes. Meteorites are fragments of heavenly bodies which fall on to the earth from outer space; they show that not only do the extra-terrestrial bodies consist of the same chemical elements as the earth, but these elements compose the same compounds and mineral species, which are grouped into the same kinds of rocks. Meteorites are divided into two groups: (1) stony meteorites or aerolites, which are composed of such minerals as olivine and bronzite, that are found in the rocks of the earth's crust,[1] and (2) iron meteorites or siderites, which consist mainly of an alloy of iron and nickel.

That the earth includes a great central mass of metallic material similar to that of the iron meteorites is indicated by its high specific gravity, which is explained by the earth consisting of a heavy core, the barysphere, surrounded by a lighter stony shell, the lithosphere.[2] The specific gravity of the ordinary iron meteorites is about 7·75, so that the earth's specific gravity of 5·7 indicates that the metallic exceed the stony constituents.

The comparative thinness of the lithosphere is also indicated by radioactivity. The earth is radioactive to an extent that can be explained by the limitation of its radioactive minerals to a shell of about 40 m. thick. Among the few materials that are not radioactive are the iron meteorites. Hence the radioactive phenomena of the earth are consistent with its structure as a stony shell of about 40 m. thick surrounding a core of nickel-iron.

This conclusion was first suggested from the propagation of earthquake waves. The late Prof. Milne was thereby led to the conclusion that the earth consists of a rocky shell about 40 m. thick, and of a denser, more rigid core, composed of a material which he called "gelte," and which he regarded as mainly composed of nickel-iron, like the iron meteorites. Later study of the distribution of earthquake waves by Dr. R. D. Oldham has shown that within the barysphere is an inner core, which occupies about a fifth of the earth's diameter and does not transmit earthquake waves. This centrosphere in that respect behaves like a gas.

Various lines of evidence therefore together indicate that the earth probably consists of a centrosphere which may be gaseous; of an intermediate layer, the barysphere, which forms the bulk of the earth and consists mainly of nickel-iron; and of an outer shell, the lithosphere, which is probably about 40 m. thick, and forms the rocky crust of the earth. This structure would be the natural result from the condensation of a swarm of small heavenly bodies with the average composition of the meteorites. How the swarming may have happened we have to inquire from cosmogony, which presents two rival hypotheses: the nebular theory attributes the earth to a cloud of white-hot gas, and the meteoritic theory to a swarm of cold meteorites.

According to the nebular theory of Laplace the solar system was originally a cloud of incandescent gas that extended beyond the orbit of its outermost planet; as this mass cooled and contracted the matter collected into rings, like those around Saturn or of the Ring Nebula in Lyra. All the matter in each ring was gradually collected into a planet and its satellites, which continued to revolve around the sun along the circle occupied by the ring from which they were formed. As the outer zone of the nebula cooled first the central mass has remained the hottest, and thus the sun is nearest to the condition of the original nebula. This theory brought into one logical and consistent scheme so much observational material that it was almost at once accepted, and for a century and a half dominated speculations on the history of the solar system and interpretation of the heavenly bodies. Further observation by improved telescopes discovered important facts consistent with the theory. The nebulae include bright compact clots indicating local concentrations of material, and also empty spaces, such as the Eyes in the Owl Nebula. Many nebulae rotate, for the rays of the spiral nebulae are bent backward; nebula M 101 is estimated to rotate once in 25,000 years. Further coincidence with the requirements of Laplace's theory is that the nebulae are not spherical but disc-shaped; that in Andromeda, being seen obliquely, appears elliptical, and that in

[1] The elements proved by Sir William Crookes (*Phil. Trans.*, 1918, vol. 217A, pp. 427–30) in the stony meteorites include iron, chromium, magnesium, nickel, silicon, sodium, manganese, potassium, aluminium, and calcium, in addition to oxygen, hydrogen, and carbon; so that they consist of the elements which form the bulk of the earth's crust. The proportions of the four chief constituents of many stony meteorites are so similar that Sir William Crookes (*ibid.* p. 426) suggested the possibility of their all having been derived from the disruption of one planet intermediate between Mars and Jupiter, while he suggests that the nickel-iron meteorites were of a different origin or derived from the core of the same planet.

[2] The mineral species found in aerolites are characteristic of the basic rocks; but the existence of acid meteoritic material has been claimed, from the obsidianites found chiefly in Australia. These obsidian buttons have forms found also in fused dust-dust; their microscopic structure suggests that they are due to the fusion of dust by lightning during dust storms, and that they are aerial sublimates.

Berenice's Hair, seen edgewise, appears as a line with a thickened centre; Laplace's theory explained why, with a few insignificant and intelligible exceptions, all the bodies of the solar system travel round the sun in the same direction and nearly in the same plane, for it represents them all as having been part of one lens-shaped mass.

The spectroscope added striking support to the nebular hypothesis by Huggins' discovery in 1864 that the nebula in Draco consists of incandescent gas; while later proof of the solidity of the material in spiral nebulae is consistent with their representing a later stage than that of the nebula in Draco. Such nebulae would include white-hot particles, though the average of the mass would be cold. The spectroscope also revealed the fact that the different heavenly bodies consist of similar materials. Most of the terrestrial elements are known in the sun, in which hydrogen, calcium, iron, carbon, and sodium are especially conspicuous. It is true that the only material yet recognised by the spectroscope in some nebulae is the light gas, nebulium, and that the solar corona consists mainly of coronium; both these elements are unknown on earth. Despite such exceptions the spectroscope has demonstrated the uniformity of material throughout the solar system and the general unity of matter.

Laplace's theory was therefore regarded as firmly established by astronomical observation finding so many agreements with its requirements. Weighty mathematical and physical considerations, however, tell against it. A cloud of white-hot gas as tenuous as a nebula and surrounded by the intense cold of outer space should cool almost instantaneously. The luminosity of the nebulae is one of their still mysterious properties. "We have no knowledge," says Hale (*Stellar Evolution*, 1908, p. 206), "why they glow with a steady and unchanging light, since there is no direct evidence that this light is produced either by heat or by electrical excitation."

The objections to the nebular theory which have carried the greatest weight are those founded on the distribution of energy in the solar system. Jupiter possesses only 1/1000 of the total mass of that system, yet possesses 95% of the total energy of rotation. The mathematical objections are regarded by Chamberlin, Moulton and See as absolutely fatal to the theory, while Jeans remarks (*Problems of Cosmogony*, 1919, p. 274), "it seems probable, although by no means certain, that we must abandon the Nebular Hypothesis of Laplace." According to Hale (*op. cit.* 1908, p. 186) it must be reconstructed or abandoned.

The chief rival to the nebular theory is the meteoritic theory, which regards the various stellar systems as formed, not by the cooling of clouds of incandescent gas, but by the aggregation of innumerable small meteorites. The meteorites coming together are heated by collision and pressure until they are fused into a solid mass. The meteoritic theory has three chief forms. The first, due to Sir Norman Lockyer, trusted to the infinite numbers of meteorites in space to provide ample material for the star systems. The numbers are indeed infinite. Any observer may see about seven per hour on any moonless, cloudless night, and from this number it is calculated that from 10 to 15 million enter the earth's atmosphere every day. It has been calculated that they occur through space on an average of 200 m. apart. Most of those which fall on the earth are minute, and they are pulverized by friction with the atmosphere into dust, the quantity of which is relatively so small that it would take aeons for the earth to add one cubit to its diameter by this process. The earth may, however, have formerly received more of this material, as it is travelling along a path which has now been swept clear of meteorites; it is chiefly those that are travelling on irregular paths through space which fall upon the earth, though Sir Norman Lockyer recognized that many meteorites travel round the sun on regular orbits like minute planets. The objection that the number of meteorites is too small and gravity too weak to collect them into swarms led to a second form of the hypothesis—the planetesimal theory of Chamberlin (*Geology*, vol. ii., p. 4, 1906). He assigned the chief constituents of the planets to meteorites which are moving in orbits around a common centre. He described them as "infinitesimal planetoids or planetesimals." The theory in this form had the attraction that it explained the segregation of the meteorites, but in his later statement of it (*Origin of the Earth*, 1916) the planetesimals are relatively unimportant and the planets are attributed to clots formed in rays shot out from a star which has been disrupted by the close approach of another star. The constituents of these clots revolve around a secondary centre and are minute satellites, not planetesimals. If a star be thus disrupted two antipodal rays would be projected from it, and during its rotation the ends of the rays would lag behind as in spiral nebulae; the segregation of the material in the rays into clots would produce the planets.

A third form of the meteoritic theory, that of T. J. J. See, represents space as originally crowded with meteoritic dust which has gradually collected around larger bodies and thus slowly built up star systems.

All varieties of the meteorite theory agree in assigning the origin of the earth to an aggregation of cold meteorites which have been welded into a solid body by collision and pressure. This theory seems to offer the most probable explanation of the origin of the earth, but the form that is most likely to gain acceptance is uncertain. As Mr. Jeans remarks (*op. cit.* p. 288), "the time for arriving at conclusions in Cosmogony is not yet come." The evidence available, however, justifies the conclusion that the world is an iron projectile, hardened, like those of modern artillery, by nickel, and whirling through space; that it was probably due to a swarm of meteorites, which fused into a compact mass; and that during its consolidation the metals settled downward into the core, the barysphere, while the lighter stony materials floated like a slag to the surface and there solidified the lithosphere or crust of the earth.

*The Origin of Life on the Earth.*—The physical conditions on the early earth also bear on the problems connected with the origin of life on it, which has been explained as introduced from some other world. The conditions on the earth were probably as favourable to the independent generation of life as any we can assume elsewhere. The formation of living from dead matter by processes still in operation has been claimed as probable by Sir E. A. Schafer in his presidential address to the British Association (1912); but it more probably happened in the early days of the earth under the special atmospheric and climatic conditions which prevailed in primeval times.

Living matter consists mainly of compounds of carbon, many of which have been made artificially. The carbohydrates can be made by inorganic processes and also altered into the more complex amino acids, which are the physical basis of living tissues. A carbonaceous jelly which has many of the properties of living matter can be made artificially, and would probably have been formed naturally under the conditions prevailing when the earth was young. The vitalization of this inorganic material would have resulted from the formation of a catalytic agent concentrated in a small spot or nucleus, which would control the subdivision of the growing mass of jelly when its size became too large to be stable. Chemical research on the carbon compounds has shown that there is no insuperable difficulty in the production of organic materials from non-living matter, without the intervention of a living organism. The process by which the non-nuclear carbonaceous jelly was developed into the primitive organism Protobion, as it has been called (Gregory, *Making of the Earth*, 1912, p. 231), by the development of a nucleus which acts catalytically probably through some phosphoric constituent, is the gap still left in explaining the origin of life. The environment on the muddy shores of the primeval sea, when the atmosphere was richer, warmer and moister than that of the present day, and changes of temperature were slight, would have been especially suitable for this momentous development.

*Geological History in Relation to Cosmic Theories.*—Life once established would probably have developed steadily since the earth's surface comparatively soon reached an average temperature and climatic conditions which have persisted throughout later geological times, though there may have been rhythmic minor oscillations. The geological history of the earth is better concordant with the meteoritic than with the nebular hypothesis. On the latter would be expected a series of progressive changes throughout geological time, the climate becoming colder as the sun and interior of the earth cooled, volcanic activity diminishing as the crust thickened and the surface of the fluid rock material lay deeper, earth movements losing vigour though generally following the same lines, and the oblateness of the earth increasing as the equatorial bulge enlarged under the unceasing influence of rotation. It has also been held that the age of the earth must be comparatively short owing to the limited heat supply in the solar system.

Calculations as to the age of the earth based upon the rate of the loss of heat from the sun led to the belief that its duration must be relatively short, and the estimates have varied from possibly as little as 13 million years to perhaps as long as 100 million years. The recognition of other sources of heat, such as atomic disintegration, has, however, released geology from the short mathematical limits on the age of the earth.

In a paper by Prof. H. N. Russell, read before the Royal Society, March 10 1921, the estimated age of the earth was given between 2,000 million and 8,000 million years. Geologists and cosmogonists now assume practically as great an age for the earth and the solar system as they find convenient, and 1,000 million years is a moderate minimum.

The progressive changes that would appear to be the natural consequence of the nebular theory are not indicated by geological evidence. Instead of a steady advance throughout the ages there

have been rhythmic oscillations about a general average. Thus the climate of the earth as a whole has been of about the same order throughout geological time; the oldest sandstone in the British Isles, the Torridon sandstone, was formed under desert conditions, and the size of its grains and the position of wind-polished surfaces on the pebbles show that the wind was of the same power and had the same prevalent direction as at present. The evidence of some of the oldest rocks shows that in the earliest geological times glacial conditions prevailed in parts of Canada, Spitsbergen, and North Siberia, while a little later (in the Cambrian period), central China was glaciated and ice floes floated in the seas of Australia up to the tropics. The climate of the world in the earliest geological periods was therefore no warmer than that of to-day. In Carboniferous times prolific vegetation grew the materials for the world's chief coal-fields, but at the same time glaciers existed in central India, south-eastern Brazil, South Africa and Australia.

Similarly, volcanic action shows no steady decline in power; periods of world-wide volcanic activity due to violent disturbances of the crust have alternated with periods of general volcanic rest.

The shape of the earth has doubtless throughout geological time been approximately an oblate spheroid, but it has been deformed to an irregular geoid by the hard crust sinking in places to follow the shrinkage of the internal mass. The excess of crust was most readily disposed of by subsidences on four surfaces producing the oceanic basins, while raised areas antipodal to the depressions formed the continental masses. The major subsidences have thus produced periodically a tetrahedral deformation, which was corrected, whenever sufficiently developed to render the crust unstable, by spheroidal recovery accompanied by relatively quick and tumultuous earth movements. These major subsidences and uplifts have been accompanied by the buckling of belts of the earth's crust into the great fold mountain chains; these movements happened at four main periods of mountain formation, represented by the Grampian folding of north-western Europe in the pre-Cambrian; the Caledonian movements at the end of the Silurian; the Hercynian, which at the end of the Carboniferous produced the older east-to-west mountain chains from Asia across Europe to North America; and the Alpine-Himalayan and west American mountain systems in the middle of the Cainozoic. Each of these great periods of earth movement was followed by intense climatic disturbance with local glaciations, and rapid biological evolution. Temporary changes in the environment were intensified by rearrangement of ocean and continent due to crustal movements across the older geographical structures.

Earth movements have not only determined the major elevations and depressions of the crust, but also the secondary depressions, such as sunklands, due to the subsidence of areas along peripheral faulting, rift valleys due to sinking of bands of country between parallel faults, and fiords due to formation of valleys along intersecting fractures when broad areas of hard rock have been raised in dome-shaped uplifts (Gregory, *Origin of Fiords*, 1913). The one change on the earth that has been apparently progressive has been the restriction in space of violent crustal movements. The Eozoic rocks, those of the older pre-Cambrian times, are steeply tilted in all parts of the world. Later rocks are often nearly horizontal, and steep tilting in them is confined to belts connected with mountain-forming movements; for with the growing strength and thickness of the crust the movements necessary for its accommodation to the reduced size of the earth have been concentrated along narrow bands.

The probable future changes in the nature of earth movements may be inferred from the study of the moon, which of all heavenly bodies is perhaps of most interest to the geologist, as, owing to its proximity, it is the one of which we have fairly precise information as to its topography. The map of the visible side of the moon is indeed more complete than that of the earth. The topography of the moon, like that of the earth, includes wide sunken areas, the "maria" which correspond to oceanic basins, long narrow mountain chains which are composed of parallel ranges, and volcanic craters, some of which are apparently still active. The most characteristic features of lunar topography are numerous ring-shaped mountains named vulcanoids; they surround circular or polygonal depressions and may correspond to volcanic caldrons, but are much larger than those on earth. They were first regarded as volcanic craters, but their intimate structure shows that they are composed of concentric ridges and neither of radial lava flows nor piled rings of volcanic ash. They have also been interpreted as impact rings raised by the fall of colossal meteorites; a theory which, however, does not account for their distribution. The moon differs from the earth by the mountain chains being relatively fewer and more fragmentary. The moon probably had a similar early history to that of the earth, but passed through the early stages more quickly because as a smaller body it cooled faster and acquired a thicker and less easily folded crust. It has apparently no shell resting upon a plastic layer, by sliding over which it can accommodate itself to changes of shape rendered necessary by the contraction of the interior. Owing to the absence of this frictionless layer and occurrence of the tremendous monthly changes in temperature the vertical movements on the lunar crust are more important than the horizontal. The chief younger lunar mountains are due to the vulcanoid subsidences, not to the crumpling of narrow belts. The ridges on the moon which appear to be fold mountains are old and broken, for it has reached a stage in which their formation has either ceased or is decreasing. The moon moreover, as it rotates on its axis only once in each month instead of daily, is practically cold, and has not the fairly constant belt of heat round the equator which exists in the earth's geography.

The moulding of the moon's surface by denudation must be very different from that on the earth, the moon having practically no atmosphere and no surface waters, its rocks are not subject to ordinary decay and wear, but, owing to the absence of an atmosphere and its day lasting for a fortnight, it undergoes violent changes of temperature which must shatter the rocks and cause the fragments, by their lengthening and contraction at every change from day to night, to creep down even gentle slopes. The level areas on the moon are therefore probably covered by a sea of talus which spreads over them like the flow of the stone rivers of the Falkland Is., but is effective on gentler gradients.

The aspect of the moon indicates the probable future of the earth when, by continued cooling of the interior, the crust has become much thicker and more rigid. Its condition forecasts the state of the earth at some future time when its relief will be due almost entirely to vertical movements as the crumpling of belts of the crust will have ceased, and when horsts and sunklands due to faulting and valleys due to subsidence instead of to erosion will be the dominant features in the topography.

(J. W. G.)

## II. Dynamical Geology

*Volcanoes* (*see* 28.178, 11.657).—The most important later advance in our knowledge of the processes of volcanic activity is in the study of the gaseous emanations of volcanoes. These have been somewhat elaborately investigated in regard to Kilauea. Water vapour was found even in the gases most directly collected from the central lava column, associated with permanent gases, consisting mainly of carbon dioxide and monoxide, sulphur dioxide, nitrogen and hydrogen, with some free sulphur, chlorine, fluorine and perhaps ammonia. This group of gases, associated together at a temperature of 1000° C., cannot be in equilibrium; the hydrogen could not exist, except temporarily, in presence of the dioxides of carbon and sulphur, nor the free sulphur in the presence of carbon dioxide; chemical reactions would take place, all of which are accompanied by the evolution of heat. Other reactions, between the gases and the protoxide of iron in the lava, equally give rise to the evolution of heat, and in this is found an explanation of Brun's experience that when obsidian is raised to the temperature at which gases are freely evolved nothing can stop its expansion into pumice, the accession of heat from within, owing to chemical reaction, assisting the rapid expansion of the gas by a weakening of the containing walls of the cavities. It may be added that these chemical reactions also afford an explanation of the long distances to which some lava flows have been known to travel, the preservation of sufficient fluidity being due, not merely to the protective effect of a poorly conducting shell of solidified lava, but to the continued accession of heat.

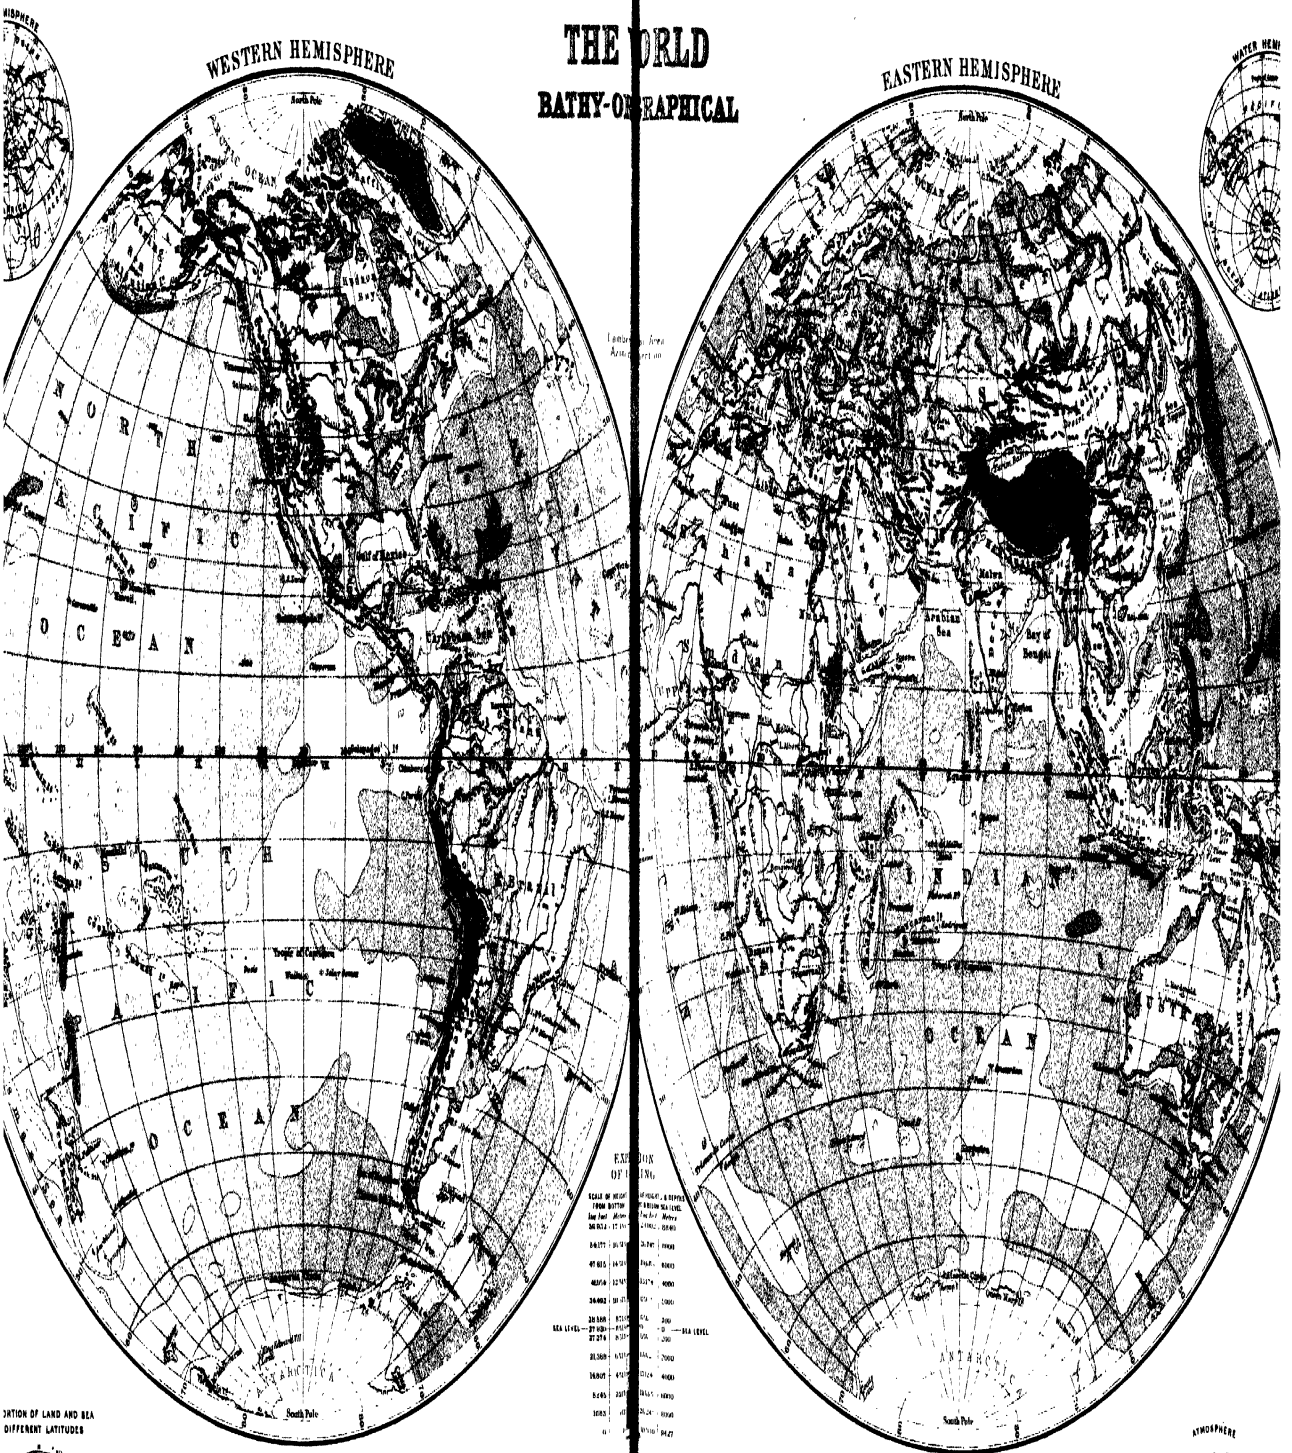
At the time of its appearance much attention was attracted to A. Brun's theory, that the volcanic exhalation was essentially anhydrous. Subsequent investigations, especially on Kilauea, have not borne out his contention in detail, and the theory has been generally rejected, at any rate in English countries; yet there is a probability that it may not be far from the truth, so far as paroxysmal eruptions are concerned. The generally accepted opinion, that the propulsive agency in these is predominantly steam, seems to be due to the resemblance in form between the cloud formed over a volcano in eruption, and clouds of condensed water vapour, formed in the open air; to the presence of water vapour in the fumaroles on the sides of volcanoes, and in the emanations from lava flows; and to the occurrence of heavy rainfall in connexion with violent eruptions. The last-named is, however, by no means an invariable accompaniment, and may be readily explained by the induced upthrust of air which, in a humid atmosphere, would give rise to heavy rainfall; and as regards the first, the resemblance is equally great to the clouds of smoke issuing from a furnace. Nor can dependence be placed on resemblances, for clouds may be caused by other vapours than that of water, and one formed of such vapour, mixed with the impalpable dust of an eruption, may be indistinguishable in appearance from the ordinary aqueous clouds of the atmosphere.

Direct observation is ordinarily impossible in a violent eruption, but, in 1911, G. Ponte was able to collect gas issuing from a fissure, outflow of lava, derived directly from the column of lava in the central neck of the volcano, then in violent eruption. Analysis of the gas showed it to be composed mainly of carbon dioxide, with some nitrogen, sulphurous acid, sulphuretted hydrogen, nitrogen oxides, muscalde and methane but no water vapour. This observation is confirmatory of Brun's contention, and, even as regards Etna, there are some general considerations bearing on this question. Water is one of the end products of the reactions between magmatic gases

which have been referred to above; the eruptions of Kilauea are of a different type, in which many of these reactions have taken place before the gases escape, and observations show that the percentage of water vapour is less in those collected most directly from the lava as it ascends from the central pipe, dropping to only 4% in the collection made most directly from the boiling lava. In more violent eruptions, where the gases issue more nearly in the composition with which they are released from the magma, the proportion may well be less than this, and even drop to nothing. Brun's observation that the fumaroles nearest the crater of Vesuvius, having temperatures of 400° C. or more, yield very small amounts of water vapour, has been confirmed by Perret on Vesuvius and Ponte on Etna, but the most pertinent fact is, probably, the presence of chlorides of iron, magnesium and aluminium in the ashes of the cone, and within the crater, after violent eruptions of Vesuvius. Being deliquescent these minerals could not have crystallized in the presence of saturated steam, and equally could not have been formed in the presence of superheated steam, as they would then have been decomposed with the formation of oxides, at temperatures even below 500° C., much lower than that of the escaping gases of the eruption. There is, therefore, reason to suppose that water vapour, as such, may be absent from, or form a trivial proportion of, the gases issuing from the vent of a volcano in violent eruption; it would be formed, after issue, as the result of reactions between the components of the highly heated ascending column of gases, and by union of hydrogen with the oxygen of the atmosphere. This supposition is, moreover, in keeping with the modern trend of conjecture regarding the nature of the fluidity of the magma, according to which the effect formerly ascribed to water is now frequently attributed to hydrogen, either free or in combination with other elements than oxygen.

*Earthquakes* (*see* 8.817, 11.659).—Not much has been added in more recent years to our knowledge of the character and effects of earthquakes. The ultimate cause is still very incompletely understood, but it has become clear that *faults*, of structural geology, are much less directly connected with earthquakes than was formerly supposed. It still remains established that the vast majority of earthquakes are caused by the shock resulting from dislocation of the solid material of the earth's crust, due to fracture consequent on a state of strain, but the detailed examination of the Californian earthquake showed that this strain was radically different in character, and the result of some quite different cause, from that which produced the San Andreas fault, along which visible displacements took place. The earthquake was not, in fact, an incident in the growth of the fault, nor the fault the cause of the earthquake; the real connexion of the two being that the fault produced a plane of weakness, along which relief of the growing strain took place, and so controlled the local distribution of the intensity of disturbances. It is probable that detailed investigation would yield a similar result in the case of other earthquakes, where a visible connexion between the violence of the earthquake and the existence of structural faults has been observed, for another result of the examination of the Californian earthquake was to show that the fracturing of the crust, to which the felt earthquake was due, was but the secondary result of a more deep-seated disturbance or bathyseism, and that this bathyseism, the exact character and depth of which are still unknown, gave rise to the long-distance records commonly attributed to the earthquake proper (*see* Seismology). Though, as has been said, nothing is known of the character of the bathyseism, it may be connected in some way with the changes of volume consequent on a redistribution of the chemical elements composing the material in the interior of the earth, which are referred to in the section dealing with the origin of mountain ranges; according to the ingenious speculations of Mr. W. H. Goodchild it is probable that some of these changes may take place with great, even explosive, rapidity, and so might easily give rise directly or indirectly to both the earthquake proper and the long-distance record.

The study of the periodicity of earthquakes has given some curious and interesting results. According to the tabulation of 20 years' record of the Italian seismological service there is, in Italy, a well-marked diurnal periodicity, giving a well-marked maximum frequency at about two hours after midnight, and a period of low frequency extending from about 9 A.M. to 5 P.M. with a minimum at about two hours after midday, the maximum frequency being almost twice as great as the minimum and the number of earthquakes occurring during the 12 hours of the night being very close to half as many again as the number recorded during the 12 hours of the day. The subject has been elaborately investigated and the periodicity shown to be a real one, not to be accounted for by any imperfection of the record. Though certainly real, the particular form of periodicity applies only to Italy, other regions differing in this respect, and no satisfactory explanation has been offered. It is evidently not due to tidal stresses set up by the attraction of the sun, for the periodicity completely disappears when the record is tabulated by lunar instead of solar time; there is, however, another peculiarity of frequency which does seem attributable to this cause. In any record of sufficient extent to be usable, it has been found that the relative proportion of day shocks to night shocks is slightly greater during summer, and slightly smaller during winter, than the general average for the whole year. The variation from the mean is small, not exceeding 6% in the most extreme case which has been investigated, and is generally less; it can only be detected when a large number of records are investigated, but as the same relation has been found repeated in the only two cases where the record has been discussed in terms of lunar hours and declination, it may be accepted as real, and very probably connected with the different distribution of the tide-producing stresses during the day and night, according to the varying declination of the sun and moon. Whether this conclusion be accepted or not, the very smallness of the effect shows that earthquakes are uninfluenced, except possibly, and very insignificantly, as to the actual time of occurrence, by any cause exterior to the earth; they are a purely terrestrial phenomenon, due to actions which take place within the outer crust of the earth and, therefore, the study of them is distinctly a branch of geology.



*Origin of Mountains* (*see* 11.659).—The problem of the origin of mountain ranges, and incidentally of the major inequalities of the surface of the earth, stands in a very different position from that which it held in 1910. At that time it was recognized that in some of the elevated tracts of the earth there was no obvious connexion between geological structure and orography, but in other cases, of which the Alps were a type, it had been observed that there was very intense disturbance and compression of the rocks, that the strike of the folds, into which the rocks had been thrown, agreed with the general direction of the range; and in these cases, regarded as "true" mountain ranges, it was believed that the surface elevation was due to a thickening of the crust consequent on the compression indicated by the disturbance of the rocks (*see* Plate).

Even in the Alps there were difficulties: the compression is not simply towards the principal crest of the range, but large blocks of strata had been thrust from the southern limit of the range to near the northern, and though it was possible to explain this by a gradual southward migration of the central axis of compression many difficulties arise in the course of such explanation. Another point, which could not easily be met, is the want of a relation between the degree of compression and the height of the mountains. The Himalayas, also regarded as a true mountain range of Alpine type, are about twice as high as the Alps, but the amount of compression of the rocks is, if anything, distinctly less. In the course of the decade 1910–20 other ranges were studied; the Andes are now known to exhibit much less compression of the strata than the Alps, less in fact than many lowland regions which give no indication of having ever formed lofty mountains; but the most striking case of want of accord between the geological structure of rocks and the relief of the surface is in the region of the Pamirs. Here, between the plains of Russian Turkestan, on the W., and of Chinese Turkestan, on the E., and between the upper waters of the Jaxartes and Oxus, on the N. and S., is a great mountain mass, in which the general course of the ranges and river valleys, as of the trend lines of the geological structure, is between S.W.-N.E. and W.S.W.-E.N.E. From the low hills on the west the general level of the surface rises to the high plateau of the Pamirs, and eastward of these comes a well-defined mountain range, the Mustagh Ata range, with peaks ranging to over 25,000 ft., running nearly N. to S. along the edge of the plains of Chinese Turkestan. So well marked and definite is this range that the late Prof. Suess, in his great work on *The Face of the Earth*, concluded that it must be structural, and that the trend-lines of structure as seen to the westward must bend round to follow the course of the mountain ranges. The earlier observations of Dr. F. Stoliczka, and the recent explorations of Sir Henry Hayden, have alike shown that this is not so, and that the general strike on the Pamirs is continued across the range to the plains of Chinese Turkestan.

In both of these mountain regions, the Andes and the Pamirs, and especially in the latter, large parts of the surface show the rounded outlines and moderate slopes of a lowland topography which has been subject to a prolonged period of subaerial denudation, the mountainous character, where present, being due to quite recent erosion by streams and rivers. In other words, the indications in both regions are that the present elevation is due to a simple uplift, quite independent of, and of later date than, the compression which is evidenced by the surface rocks. In parts of the central Himalayas there is evidence leading to a similar conclusion, and most of the difficulties in reconciling the structure with the larger features of the surface relief of the Alps would disappear if it were accepted. Meanwhile, an entirely different line of research had led to a simil-

...ter results. It has long been known that the apparent excess of matter in the visible prominence of mountain ranges was compensated by a diminished density and consequent deficiency of matter in the crust beneath them. The elaborate studies of Messrs. Hayford and Bowie, Becker and others, have shown that the principle is of wider extent, and that whatever the relative height of the surface may be the amount of matter under any region is approximately equal, the greater volume indicated by greater surface elevation being compensated by a lesser average density. To this general principle the word *isostasy* is now generally applied, though the term was originally intended to indicate the process by which the result was brought about. The geological application of this conclusion, derived from geodetic observation, has been elaborately investigated by the late Prof. J. Barrell, who concluded that the strength of the earth's crust as a whole was about double that of good granite as we know it, that the thickness through which this strength continues is about 30 m., and that below it there is a rapid transition to material not much more resistant to change of shape than lead. He also calculated that the average departure from exact balance of surface relief and compensation, in the continental region of N. America, is equivalent to a load of average rock reaching a maximum thickness of about 1,600 ft., and thinning out to nothing at the ends of a length of about 200 m.; for a greater length the maximum load would be correspondingly less, and greater for a shorter length. This does not indicate the maximum possible departure from exact isostasy, for even within the American region he finds evidence of about double (in the Pacific islands quadruple) that shown by the figures quoted.

The bearing of the recorded geodetic observations on the origin of the Himalayas and Pamirs, the largest and loftiest mountain region of the world, has been investigated by R. D. Oldham. He found that the excesses and deficits of matter indicated by observation were ranged in alternate bands, following the general course of the major surface relief; that the outer hills of the mountains bordering on the lowland plains showed an excess of matter; that farther in towards the centre of the hills this was followed by a zone of deficiency of matter, and that (though observations are wanting here) the most central portion is either in equilibrium or may show some excess of matter. The widths of these zones, the amount of the departure from exact equilibrium, and the distribution are very much the same as those which would result if a crust of the strength found by Prof. Barrell were uplifted by expansion of the material underlying, or possibly composing, its lower portion. Such an expansion of the underlying material, being necessarily accompanied by decrease in density, would not only account for the compensation of the elevated region, but assumes a prominent position as the primary phenomenon, and direct cause, to which the elevation of the mountain mass was due. This idea is not new, but while the only explanation of the changes of density was variation in temperature, the cause was, quantitatively, inadequate. Of late years, however, a new aspect has been given to the problem by Dr. L. L. Fermor, who has shown that a magma of the same chemical composition may solidify in more than one form of mineral complex, and that the density, and solid volumes, of these aggregates may vary by 10 to 30 per cent. To the two different forms of solidification he applied the terms plutonic or infraplutonic, and pointed out that the transition from one to the other form of mineral combination of the same chemical elements would depend on the balance between pressure and temperature; so that a small change in either might result in a passage from one mode, or mineral combination, to another of the same norm, or magma, and that this passage would be accompanied by a very considerable change in bulk, which, again, would result in uplift or sinking of the surface level. As the variations in underground density revealed by geodetic measurements are not greater than those provided for by Dr. Fermor's supposition, it is evident that we have here at least one cause which would at the same time account for the major inequalities of surface level, and for what is known to geodesists as compensation.

We have, then, an agreement between two independent lines of research, one pointing to the conclusion that the greater inequalities of surface level are the result of underground changes in density, the other indicating with a high degree of probability that such changes do occur. It must, however, be added that a detailed study of published geodetic measurements suggests that this explanation is not quite complete, and that, as suggested by Dutton, the surface transference of material from regions of denudation to areas of deposition is accompanied by a corresponding underground transfer in the reverse direction; yet the effect of any such transfer is subsidiary and trivial in comparison with that of the changes of density to which the predominant proportion of the changes of surface level appear to be due.

This explanation is in accord with the fact that the larger features of the surface forms of the earth, such as the distinction between continental and oceanic areas, cannot be fully accounted for in terms of surface tectonics alone. It does not touch the importance of these tectonics in determining the secondary irregularities of relief; the well-established connexion of climate with geological structure of the surface rocks, on the one hand, and the processes of denudation and deposition, on the other, is unaffected, and it will remain possible that within limits hills and ranges may be directly due to compression of the solid enveloping crust. These questions may be dealt with precisely, but as far as present knowledge goes we may look at the extreme figures of a breadth of 200 to 300 m. and a height of 20,000 to 30,000 ft. for a narrow band the length of which is increased, for a greater width it would be less. These figures, though necessarily vague, give an idea of the limit of magnitude which can be allowed for surface inequalities resulting from superficial tectonic forces. For the larger features—the lofty mountain ranges, the deeps of the ocean, the extensive elevated plateaus and the broader distinctions between ocean and continent—we must look to causes and changes operating in the more deeply seated portions of the crust, or in the material underlying it.

## III. STRUCTURAL GEOLOGY

*Isostasy.*—During recent years, the consideration of the structure of the outer layers of the earth's crust, and of the relation between areas of elevation and depression, has been greatly influenced by the doctrine of *isostasy*. It has been felt that the larger inequalities cannot be supported by the rigidity of the crust. They may, however, when once they have been established, be maintained on a yielding crust by transference of load. The processes of denudation carry material from the uplands to the lowlands, and ultimately to the ocean basins, thereby lightening the upraised regions and increasing the weight on those already low (see Plate). The down-bent areas thus become further depressed, while mountains and continents rise as a consequence of their own decay. C. E. Dutton, who invented the word in 1889, has defined it as "the tendency to maintain mountain profiles in equilibrium" (*ἴσος*, equal, *στάσις*, condition).

A simple case of isostatic response to change of load was suggested by T. F. Jamieson in 1865 (*Quart. Journ. Geol. Soc.*, vol. 21, p. 161) when he explained the raised beaches of northern Europe as due to the depression of the region by the weight of ice in the Glacial epoch, followed by an upward swing of the crust when the burden was removed by melting. Jamieson's view has been extended by N. Otto Holst (1914), who points out that the subsequent rise may have been a second though minor glaciation, followed by renewed subsidence, the final melting brought the various beaches to their present elevations above the sea. It will be seen that the theory of isostasy does not preclude slow irregularity of bulging, and is altogether more satisfactory than one which seeks to account for raised beaches by a general change in volume of the sea. The matter is carried further by those who trace a movement of elevation contemporaneous with the northern depression in regions S. of the loaded areas. Fr. Nansen (1910) thus accounts for the uplift of the floor of the Pliocene sea in the Mediterranean basin, whereby shells have been carried to heights of 1,750 metres above the present level of the Aegean. H. Munthe (Internat. Geol. Congress, 1910, *Resumés et Table*, No. 9) suggests a similar bulging for the periphery of the glaciated area of northern Europe, and a reboundent belt in the more southern region now rising. Isostatic recovery in W. N. Johnson's view in Canada, may be concealed in certain places by the filling of valleys with water previously tilted up to sea-level. R. A. Daly indicates that, after a general lowering of sea-level due to a recurrence of cold, a mild lapse towards the former general rise of the sea-level takes place in many (but not all) districts of the Pacific. Recent continental elevation of the water-level, as well as subsidence, are important factors to be allowed for in connecting raised beaches with [illegible]

J. H. Pratt (*see* II. 654) in 1855 laid the foundation in India for a generalization that has been widely accepted as an explanation of the support of mountains. He pointed out that observations on the deflection of the pendulum from the vertical indicate a defect of mass in the Himalaya range and an excess of mass towards the Indian Ocean, and he concluded that highlands were upheld by difference of density in the crust. Detailed work is still in progress; but numerous observations with the seconds pendulum, and by comparison of points and mercury barometers at sea, already serve to indicate a general "positive anomaly" of gravity—that is, an excess of attraction in the oceanic areas. The "negative anomalies" associated with high plateaus and mountain-chains are compensated by positive anomalies in adjacent plains or under adjacent seas. It is held that denser rocks, such as basaltic magmas, have accumulated beneath the oceans, while mountains are typically formed of less dense material. They may thus be compared with floating bodies; they are supported by the pressure of denser masses which they have in part displaced. At a certain depth below the less dense earth-block under an elevated area, and below the denser earth-block under an adjacent area depressed below sea-level, a region of *compensation* must exist, where the two blocks balance one another. If of equal area, these two blocks above this "depth of compensation" will contain the same mass. To geologists, who realise the complexities of intrusion, and the interlocking of various types of rock in the outer layers of the crust, the conception of columns of uniform density stretching down from the surface to the depths may seem too much like a purely mathematical expression; but the theory of isostatic compensation is shown by Jos. Barrell (*Am. Journ. Sci.*, vol. 48, pp. 281–338) to relate to broad areas rather than to local irregularities of the surface, and it is probable that the balance is attained much more nearly under continents than under isolated mountains. J. F. Hayford, of the U.S. Geodetic Survey, has reviewed (1909–12) the relations of topography to gravity throughout the United States, with results extremely favourable to the isostatic theory. H. S. Washington (*Journ. Franklin Inst.*, 1920, vol. 190, p. 812) supports Hayford's conclusions by an estimate of the average densities of the rocks underlying the areas of elevation and depression, including a consideration of the igneous rocks of oceanic islands and continental regions over the whole globe. G. Costanzi (1910) has correlated surface-relief throughout Europe with anomalies of gravity. E. Suess, in the concluding volume of his *Antlitz der Erde*, seriously doubts if the known range of density in rocks is sufficient to account for the maintenance of the major features of relief. His most important argument is drawn from the Indian Ocean, the floor of which represents sunken continental land. Suess points out that here O. Hecker, from his marine traverses, indicates a region of strong positive anomaly.

Albert Heim (translation in *Proc. Liverpool Geol. Soc.*, vol. 13, 1920) shows how gravity determinations in Switzerland are related to the form of the Alpine chain, positive anomalies occurring only near the Lago Maggiore and under the Black Forest. He explains the latter case by the presence of a *gravity anticlinal*, in which the denser matter of Suess's "Sima" layer is brought nearer than usual to the surface. The explanation of gravity-anomalies in the Himalayas and the "Gangetic trough" has been the subject of much discussion by Sir S. Burrard, H. H. Hayden and R. D. Oldham.

Great mountain-chains, as was long felt to be the case, evidently bulge both upwards and downwards, and send down crumpled and lighter matter from the upper crust that displaces the denser matter of the depths. This process is aided by the presence of a yielding but not necessarily molten layer, Barrell's asthenosphere, below the depth of compensation, which lies some 60 to 100 m. (say 128 to 160 km.) below the general surface of the geoid. Barrell remarks that "the density of the crust is presumably irregular in depth as well as in distribution, but it is seen to be essentially a phenomenon of the outer fiftieth of the earth's radius."

Isostasy is not put forward as a cause of mountain-building. The relative importance of successive overfolds and of vertical upheaval in establishing these features of relief is still a matter of discussion, and geologists will probably incline more and more to the view of O. Ampferer (1906) that sliding movements in the *Untergrund*, Barrell's asthenosphere, are responsible for drag and crumpling at the surface. Melting of lower layers and consequent vertical foundering may promote extensive movements in a lateral direction. At the surface the final overlapping of recumbent folds may be largely gravitational, a feature emphasized by Hans Schardt. A renewed appreciation of the importance of vertical uplift and vertical foundering leads us back to conceptions of mountain-structure that were prevalent in the early 19th century. Ampferer has even pointed out the influence of notches cut by subaerial denudation on folding that may subsequently affect the surface.

In considering folding in connexion with rock-flow, C. K. Leith (*Structural Geology*, 1914) applies the term *competent* to rocks that resist crumpling, and *incompetent* to those that yield contortions. A competent mass under increase of pressure may of course become incompetent. The flow of incompetent rocks between competent layers obviously produces considerable changes in their relations at the surfaces of contact, and complications of this kind may be expected in any crumpled series. Where faults result from overfolding, E. B. Bailey (1914) styles them *fold-faults* or *sliders*.

The recognition of overfolding of the Alpine type in other areas has been accompanied by some criticism, and H. Schardt, himself an honoured pioneer, uttered a word of warning in 1906 when he humorously described P. Termier as afflicted with *Ultra-nappisme*. E. B. Bailey (*Quart. Journ. Geol. Soc.*, vol. 66, 1910) recognized a system of recumbent folding as responsible for many features of the schistose masses in the S.W. Scottish highlands and in 1920 he described two successive *nappes* as resulting from overfolding from N.W. to S.E. L. Gentil (1918) traces three *nappes* in the structure of the coastal range of Algeria and Tunisia. In this he is strongly supported by Termier, but is opposed by J. Savornin (1919). V. Uhlig, O. Ampferer, and others have studied overfolding in detail in the Hohe Tauern and Wetterstein districts of the eastern Alps, where much attention has been given to lateral shifting across the main folds from E. to W. Maria Ogilvie Gordon (1909) indicates folds and thrusts in explanation of the relations of the dolomite masses to underlying strata in the well-known Langkofel region of Tirol. P. Termier and G. Friedel trace outlying blocks, *klippes*, the German *klippen*, separated by denudation from former overfolds of the western Alps, in the southern part of the Rhône vale and even on the flanks of the Cevennes. These outliers include a block of Urgonian strata resting on Oligocene beds and 3,700 metres long. It is held that the Gard coal-field has been affected by the Alpine crumpling, and Termier recognizes older overfolded structures of Armorican (late Carboniferous) age in the eastern border of the central *massif* of France. On the other hand, linear mountain masses may record movements that are mainly vertical. H. E. Gregory (*Am. Journ. Sci.*, vol. 41, 1916) thus treats the Andes as an uplifted plateau of marine and continental sediments, penetrated by igneous intrusions. The erosion-surface here has little regard for geological structure. This is borne out by J. A. Douglas (*Quart. Journ. Geol. Soc.*, vol. 76, 1920), who finds no overfolding in Bolivia and Peru and treats the range as a product of vertical upthrust between two resisting crust-masses. Even more recently, T. O. Bosworth records intense block-faulting as characteristic of the Cainozoic region of Peru, and a considerable Andean uplift, accompanied by a subsidence of the sea-floor, is recorded at the opening of Quaternary times. The upraised coastal band is "part of the crust-belt of the great fault." Five miles out at sea, a fault-scarp 2,000 ft. in height leads down abruptly to the depths of the Pacific. E. H. L. Schwarz points out similar features as bounding the E. coast of S. Africa, where Cainozoic shore-deposits have been elevated to a height of 1,350 ft.

*Fracturing.*—The study of structural geology has shown in recent years a marked return towards the recognition of lines of fracture, and founderings on a large scale, as influencing existing topographic features. The power of subaerial denudation has been justly emphasized by W. M. Davis in his development of the Huttonian cycle of erosion and his indication of traces of peneplains, where the eye is now likely to be diverted by later features of sculptural relief. But these later and secondary features, the walls of outstanding blocks and the courses of rivers across the rejuvenated country, are again and again associated with rectilinear and regularly intersecting fracture-systems. The tracing of rift-valleys, better styled trough-valleys, from the Jordan region to Nyasaland, and on a minor scale in the post-Oligocene groove of the Rhine from Basel to Mainz, has led to a general attempt to correlate faults and river-courses. The cliff-walls of elongated lakes in Finland are very probably due to late Cainozoic fracturing, and fault-scarps in the hard gneissic rocks guide the modern rivers on their way. J. W. Gregory in his book on *The Origin of Fiords* (1913) has collected much evidence to connect straight river-courses with more or less rectangular fracture-systems. E. B. Bailey shows the influence of downward-reaching "shatter-belts" on the valleys eroded in the region of Glencoe; and E. de Margerie gives a tectonic significance to the narrow *cluses* of the Juras, which unite the valleys of longitudinal and apparently *subsequent* streams. On the other hand, some of the surfaces cited by Gregory are connected with rock-folding and denudation rather than with faulting. J. Ball (*Geol. Mag.* 1920) points out that recent landslides have simulated fault-scarps in the Nile valley and the Gulf of Suez; both these depressions are grooves of normal erosion and not troughs. W. F. Hume (*ibid.*) regards the Nile valley as on the whole connected with the erosion of the softer Cretaceous strata in its southern part, and of Middle Eocene strata in the north. It is, however, a structural-feature in that these beds, like the carboniferous limestone in the Armorican folds of south Ireland, have been eroded along the course of a synclinal. Ball states that the Gulf of Suez is guided by an eroded anticline.

One of the most powerful influences in the correlation of surfaces

features and crustal structure has been the completion by E. Suess of the third volume of *Das Antlitz der Erde* in 1909; the annotated and "extra illustrated" French edition was published under the care of E. de Margerie in 1918. In this volume the Armorican mountain systems of Europe are regarded as offshoots of those of Asia, under the general name of Altaids. The spread of the ranges in huge southward ripplings towards India, and their finger-like ramifications in the European region, are shown, as well as their posthumous influence on the directions of the Cainozoic chains, or "Alpids."

To E. Suess we also owe the observation of "caldron-subsidences" in many portions of the globe, from crater-like depressions, such as those traceable in lunar topography, to broad plains, the gathering-ground of detritus from upstanding mountain-rings. It is true that the recognition of overfolded sheet-structure in the Carpathian ring has disposed of the conception that the differential elevation of the ring and the Hungarian basin is mainly due to faulting; but there remain many lowlands in which foundering has caused the depression, and no doubt the most striking instances are concealed beneath the oceans. The Tyrrhenian and Aegean sinkings occurred almost in human times, and speculation may still be allowed to revive the ancient tradition of Atlantis. A belief in the comparative rapidity of such movements is fostered by the evidence of Fossiliferous strata on the flanks of the marine depressions and on residual isles. The down-sinking occurred during a part of one geological epoch; and the same is remarkably true for the upheaval and lateral flow of folded mountain-chains.

The well-known Rieskessel, the plain round Nördlingen in southern Bavaria, presents all the character of a caldron-subsidence, with a core of shattered granite, and abundant upwellings of lavas on the marginal ring (*see* section in Suess, *La Face de la Terre*, vol. 3, p. 1,507). C. T. Clough, E. B. Bailey, and H. O. Maufe, in describing the "caldron-subsidences of Glencoe" (*Quart. Journ. Geol. Soc.*, vol. 65, 1909), show how foundering took place within a ring-fault, up which a "fault-intrusion" occurred, probably as a forerunner of the granite that afterwards came into the district. This intrusive rock gathered into itself the fragmental matter accumulated along the fault-plane. The mechanics of such subsidences, and the substitution of igneous matter for the foundered core, are here clearly discussed. A striking upwelling of syenite along a ring 16 m. in diameter has been mapped by W. A. Humphrey (1914) in the Pilansberg in Transvaal.
